8367. Series L/C connection with Loop Antenna

Yahoo group: loopantennas (2008 — 2012)

From: Adam E
Topic: 8367 Message: 8367

I was doing a experiment and surprisingly it worked very well with the KA-35. When I added a series L/C circuit to the loop antenna (L2) and I was able to resonate the loop antenna without connecting the the variable tuning capacitor in parallel. I did this cause I was trying to use a loop antenna without alot of turns to a variable tuning capacitor 265 pF to a 2.5 mH choke, then connected to the 470 pF to the KA-35 RF amplifer.

My results came out very well on LW, but when I was trying to calculate the L/C series circuit with a calculator and I got different readings. Is the loop antenna another inductor that is the unknown inductance that changes the calculator? How do I find the unknown inductance what algebric equation do I need to follow? If I can add that unknown inductance to the existing choke inductance to the calculator then I will know where I am tuning at.

Well, I also have a Kenwood - it is a TS-570s. I know what you mean by all the knobs, bells and whistles. My old receiver (back in the 50s) was a HallicraftersSX-25. These transceivers are really something aren't they? I also can output 1 KW on 40 into a vertical.

My plan is to erect a 500' horizontal loop and couple it with a balanced tuner that I am building. The feed point 150' away from my shack, so I am designing it to have remote control. That way I can tune it across any band.

I had read a few articles about these loops and they seemed to fit the need I have. I don't have much height (30' oak trees) but we do have lots of horizontal room. Our home is on a sloping hill so I will be lacing it through the oaks.

Hello David,

What capability do you have on 40? Also, what are the characteristics of the loop you are installing? I plan to put up a 500' loop sometime this year.

Dennis has loaned me a Kenwood TS-530S which does everything on every band with over 100 watts output. I’ve never operated such a sophisticated piece of equipment—never seen so many knobs! But it will be a while before I get my license renewed.

I’ve decided to start with a small horizontal loop (180 feet) around the perimeter of my shop. It’ll be quick, cheap, and mostly for receiving. I’ll see if I can get out with it when I get my new ticket.

The large loop that I’m planning will be around 500 ft also, with a matching stub to get it to resonate on 160. It will have to be vertical, as that is all I have room for at my end of our triangular lot. I’m a bit concerned about the radiation angles being progressively higher on the higher bands, but I’ll just see how it works on them.

Cheers,

Brian

Subject: RE: [loopantennas] Use antenna analyzer?

Hello David,

Wow. Now I remember Wayne talking about visiting a "Brian" on his way up to FB. He was talking about the big transformer he got from you.

I'm in Fort Bragg where we moved 10 years ago after 31 years in Palo Alto. Wayne

came by on a Sunday afternoon. We spent a couple of delightful hours talking about old times at Sequoia, and what we had done with our lives, and he gave me some advice about hanging up the big vertical loop that I'm planning.

The big transformer came from a diathermy machine that my podiatrist wasn't using any more. It had what looked like a pair of 813's in an oscillator circuit

at around 30 mhz. It had minimal rf shielding and must have put out at least 500

watts. A real monster. I cannibalized it, and traded off parts to the guys that could afford to build high power rigs.

Are you on the air these days and, if so, what bands do you operate on?

I let my license lapse in about 1960, and have to bone up on the latest regulations and technology. I got my general class ticket in Texas when I was 13, and had the call W5BRO. When I moved to Redwood City in '55 I got K6UCD, which Dennis Regan (K6ZJU) tells me is still available, so I will apply to get it again.

I used to work 40 meter cw, though Dennis and I had a delightful time on 15 meter 'phone. We built the $3.96 beam from CQ magazine (aluminum foil wrapped bamboo fishing poles), and borrowed a cathode modulator from somebody to plug into the keying jack of his cw transmitter. We worked stations on the east coast

with that pitiful rig, and had a ball.

Cheers,

Brian

8369. Amplified air loops

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-18 16:41:54 UTC
From: lowalacrity
Topic: 8369 Message: 8369

I have uploaded some pictures of a couple of new plug-ins for my Palomar base amp. They can be found in a new album called amplified air loops. I was impressed at how well the 4" air loop stacked up against my ferrite core heads so i decided to go big. I tried out my new 8" last night and was pleased to find it was worth the effort. It matched the performance of my best litz wound ferrite. (4 rod bundle) but only tuned down to 700 khz. Noit bad though for initial sizing. Where it really shined was on SW. Initial testing show it to be very quiet and pulled in stations amazingly well for its size. With the taps placed as shown, I was pulling in 80 meter SSB with great signal strength and clairity. Switching to the whip, signals were barely audible through the noise. I stopped a 5 Mhz where WWV was coming in loud and clear!
I'm going to try it into my Yeasu FT-757 that, with the RF gain cranked up, is extremely sensitive but then noise prone. The 8" also has a break in the center for feeding there instead of ends. The ends are then bridged. I have found this improves near field noise. More later!

8375. Ivan Board PCB

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-24 07:25:34 UTC
From: longjohn119
Topic: 8375 Message: 8375

I just uploaded a PDF file for making "Ivan Board" PCB's .... Feel free to pass this around, post to other groups or whatever so long as you don't claim personal credit for it (Whether I get credited is irrelevant to me, just that no one else takes credit for my work is all I ask)

Just print it with a laser printer with no scaling onto a A4 sized sheet of Photo Paper. (It fills most of a sheet) Cut it to the size of desired board and iron it on the copper board. (Detailed instructions for this method can be found in numerous places on the internet)

To make an Ivan Board with a ground plane I use a double sided board, iron on the Ivan Board layout on one side and they spray the other side with any cheap spray paint (Usually whatever I can get for a buck) After etching you can use paint thinner, mineral spirits, etc to remove the paint and the ironed on mask.

The Ivan Board idea came from Chris Trask who picked it up from I don't remember who. I'm building one of his loop designs and probably one of the active monopole or dipole antennas so I needed to make a couple of boards. Then I decided why waste most of a sheet of photo paper on a couple of small boards when I could just fill most of the sheet and cut off whatever I want. I have a feeling I'll be using these for other projects where I'm using a lot of surface mount devices.

So... what is it?

Could you put a better description in the File description? Look at it this way: if someone finds that file in a year, will they know what it is from your description?

Hi Bill,
I bought it soley to compare to my own broadband active loops. I saw either the same null depth or greater null depth on my loops. Likely mine don't have as good an IP3, but I have never observed any IM- even on my 7' loop.
The Wellbrook loop is very well built and well designed. But at over 10X the cost- I'll stick with my own.
The real winner on S/N so far (not counting my Beverages) is the half sized active Flag antenna
(RDF=7.4 vs 4 for a loop).

What are you using for the amplifier? I posted my own design in the files section some time ago that is at least comparable to the Pixel and Wellbrook products, and a whole lot cheaper to boot.

Hi Chris,
I believe this is a Burhans design from some years back. It uses a transformer up front to realize the low Z balanced input. I made up a dozen or so 2X PCB's and have distributed them around for guys to play with- all have had good results. Nulls appear to be of equal depth and at right angles to the plane of the loop.

It just proves- there is no magic, just good designs that can be built very inexpensively.

I just happen to be building that design right now. Hopefully I'll have it up on the roof in about a week when it warms ups a bit again. I won't be able to say how it works compared to a Wellbrook since I don't have one.

BTW what is the best way to interface a DDS signal generator/step attenuator to the input of the amp? Maybe a balun wound on one of those large 61 mix bino cores? Maybe one like the last one in the circuit hooked backwards?

I'm not really concerned about IP3 or other measurements, my spectrum analyzer is going through some rework and isn't available for use anyway. I just want to make sure it's working and I didn't make a wiring mistake before I haul it up on the roof.

Yes, very much like that though you may need to use more than one since the input impedance of the amp is just a few ohms. Do a quick check with the generator/step attenuator disconnected and then connected, from that determine the input impedance. You can easily make a 9:4, 4:1, or 9:1 UnUn to improve the match.

8386. How does the Hermes loop compare...

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-25 14:18:53 UTC
From: Editor (Kevin)
Topic: 8386 Message: 8386

Hi:

I am curious to know how the Hermes Active loops compare to the Wellbrook or other SWL type of active antennas. I know the price point is way off so that is not a point to consider.

I was wondering just about performance. The Hermes were a Canadian company that was then sold to US Antenna in Maryland.

I know the construction of the Hermes is about the most solid (rugged) I have ever seen. I was more interested in the overall system performance however. I have seen them on eBay at times.

Thanks.

Kevin

Would one of the little monolithic amps from
mini-circuits work as a rx loop amp? Down East
Microwave sells an inexpensive barebones kit (
MMICKGALI) with a GALI-74: http://www.downeastmicrowave.com/cat-frame.htm -

GALI-74 specs (
http://www.minicircuits.com/pdfs/GALI-74+.pdf)
look tempting to my untrained eye:
☐ Frequency range, DC to 1 GHz
☐ High gain, 25.1 dB typ. at 0.1 GHz
☐ Internally Matched to 50 Ohms
☐ +19.2 dBm typ. output power at 0.1 GHz
☐ High IP3, +38 dBm at 0.1 GHz
☐ Low noise figure, 2.7 dB typ.
☐ Unconditionally stable

What could be expected, performance-wise, after
matching this amp's input to the loop?

They have mediocre IP2 and are relative fragile with respect to RF overload. And because they are such broadband devices, careful PCB layout is required to avoid parasitic oscillation.

Not sure. I tried doing a wideband match to loops some time ago, and the results were pretty disappointing as you're trying to match a high-Q inductor to a resistive load. The leakage inductances of wideband transformers at very low impedances are the primary culprits, and using series tuni ng overcame that problem. Induced resistive losses were also a problem, but using powdered iron cores instead of ferrite cores took care of that. My thoughts recently have been to match the real part of the loop impedance and then add a series-resonant tuner so that the match at resonance is uniform.

Viewing the loop as a current source results in a wideband antenna if and only if (iff) the amplifier has a very low input impedance. I might approach the use of monolithic amps as a compromise, using an augmented common-base input stage as I did in that amp design and then using the monolithic amp in place of the output stage.

Chris,

Have you or somebody you know of tried the Norton amplifier configuration, only with a different turns ratio, so that it has low input impedance instead of 50 Ohm?

I know that it's entirely practical, but I've never tried it myself, nor do I know of anyone else who has. For instance, if the transformer turns rations were to be 1:1:4 (input:N:M) and the load is 50 ohms, the input impedance would be 18.75 ohms. The transformer would be made with a pair of trifilar bundles in a 1:1 turns ratio, the various wires connected in series as needed. By adjusting the turns ratio of the two bundles, you can adjust the input impedance, though there are practical limitations. You would need to make that transformer on a toroid to achieve the needed coupling between the two bundles, and you need to stick to integer ratios between the two bundles so as to have good, uniform coupling. I touched on this briefly in a 2-part series in Electronics World a year or two ago.

Making the transformer this way has interesting benefits. Since the coupling is primarily TEM m?de between the wires in the bundles and not flux coupling through the core, you improve the IMD performance of the amplifier as you are not subject to the hysteresis nonlinearities of the core material. The core provides the coupling needed for the voltage relationship between the two bundles, plus it extends the low frequency cutoff by way of the magnetization inductance.

Hello Kevin,

The Hermes loop system dates back to the sixties, when it was E M I Canada. See Wireless World May 1970 for description. Looking the US antenna website the performance doesn't seemed to have changed much!

The IMD of the these loops are about 30 to 40dB higher than the current Wellbrook ALA1530 and Pixel Sat loops under the same F S conditions of two signals at 100mV/m (web site says 10mV/m; Typo ?)

I don't have any other information.

Kind regards

Andrew Ikin

The problem with that is the output impedance of a Norton Common Base amp is whatever the input is set to (and visa versa more or less) They are great when you need/have 50 ohm in and out and Reverse Isolation (high return loss) isn't a necessary factor. I have a push pull version as the RF preamp in my SDR but I have a Common Emitter noiseless feedback amp between the filter board and the input to the QSD where I needed stellar return loss performance

There is a Common Emitter noiseless (transformer) feedback balanced circuit in the Photo section by Steve Ratz AA7U that doesn't work too awfully bad, especially for it's simplicity. The IP2/IP3 wasn't as good as my Lankford Complimentary Push Pull Active Whip but it did have a nice null so I could null out the offending AM transmitters 4.2 miles away so it worked as well or better in most cases. It's also a little noisier than I'd like, probably because the input isn't matched as good as it should be and it's biased for high IP2/IP3 and not NF. It was stable even with a 3ft diameter 3/4 OD copper tubing loop hooked up to it. (I'm a Commercial HVAC tech so I have access to tons of old refrigeration copper tubing) I had the WL1030 high speed op amp loop circuit hooked to it originally and I never good get it to be stable. Now it's the output amp for my IQ Pro DDS for a R2 Pro receiver I'm building. It's very stable there where the input is 50 ohms rather than 2-3 ohms from my loop which it didn't like at all

8397. Help? Calculation of Coax Shielded Loop Size for 3 mHz to 6 mHz

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-03-30 20:55:03 UTC
From: Ralph
Topic: 8397 Message: 8397

Gathering all my parts now and getting ready to try my second experimental loop.

Planning to build a small shielded loop using coax and a metal tuning box.

The question is what diameter to make this SINGLE TURN coax loop, if I want it to resonate from 3 mHz to 6 mHz (basically I want to use this to tune the tropical shortwave bands).

I read somewhere that a good MAX length for the loop (circumferance) would be .04 wavelength, no longer. So, if my largest wavelength is 90 meters, which sounds like 3.6 meters of wire. I'll be stuffing the coax into a hula hoop for support, so I believe the diameter of my hula hoop would then be 3.6 meters divided by pi, 3.6 meters / 3.1416 = 44 inches (3 feet 8 inches).

Questions:

1. Can some forum gurus confirm the above is going to work?
2. If I cut the coax to a length that accommodates 90 meters, how do I know it will still resonate at a higher fqy (shorter wavelength) like 6 mhz / 49 meters.

Cheers,

Ralph

See my article at:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

In the article, a 20 foot circumference loop made with foam
RG6 coax tuned with a pair of AM radio varactors is good for
about 1.6 to 5 MHz. It might go a little higher with just one
varactor, but you should probably cut back to 15 feet. Note
that 20 feet is 0.1 wavelength (in free space) at 5 MHz. I
think I remember that with no varactors at all, it resonated
at 8 MHz.

I still have some PC boards left if you want to use my circuit.
With my connectorized design, it is easy to make up different
lengths of coax and just plug them into the box and try them.
There are also provisions to jumper in different numbers of
varactors.

I also made a 40 foot version for 160 meters only, and it
had something like 9 dB more signal out.

If your location is noisy, you don't really need the big circumference. In my case, a hula-hoop about 1m diameter with a 18AWG speaker wire inside works very well on 3.5-14MHz frequencies. The noise at my location is strong, so it makes no sense to improve the efficiency. The tuning capacitor is 2 sections air variable, 400 pF each. I have a little switch that connects the second section for frequencies below 5MHz and disconnects it for frequencies above 10MHz.

A starting capacitor? You mean like one for a motor? 6uf is way too high. How did you get that number? 365 PF would be more typical.

Rick, staying with the 20' circumference, single-turn loop: if I use a 365 pfd variable capacitor, instead of varactors, will this resonate in that desired range of 3-6 mhz? (Am not sure what the specs were for the varactors you used . . .)

Also, general question: Is use of a shielded loop still popular, esp if there is a lot of electrical noise in the local area? One forum member recommends dropping the idea on shielding and just use the coax outer shield, instead, for a better conductor and more gain.

The varactors I bought from Mouser are shown here:

http://www.nteinc.com/specs/600to699/pdf/nte618.pdf

They basically replace a 365 pF capacitor (no big surprise here).
So you should be in fairly good shape. If you can't make it to
6 MHz, you can always shorten the loop a little. Be sure to use
75 ohm FOAM coax, for maximum tuning range. Using solid coax
or 50 ohm coax will reduce the tuning range substantially.

Yes that eternal debate. A non shielded loop, implemented perfectly,
will be as good as a shielded loop, and will have the advantage of
greater tuning range. A shielded loop is much less critical to
implement.

With the loop I have, 6uf is what I need for below 1KHz and I don't know enough about capacitors. The one I have I guess it's called a "run" capacitor. It says 6uf 450 volts AC. I assume I need a different type of capacitor. Well thanks for your replies.

I think I am trying to squeeze too much out of this loop, and yes, I don't know what I am doing. It was originally built for about 60KHz when using a tuning cap 365pf. So I guess I will just give up on this one.

You need a loop with more windings/inductance not a big cap. Having a way to measure the actual inductance is very helpful also ....

Those run caps do make excellent bipolar caps in speaker crossovers (The + and - marks are for phasing not DC polarity), especially for high power sound reinforcement speakers .... Otherwise not much use for them other than AC motors, if it's got a plastic case it's a start cap limited duty cycle, if it's got a metal case it's a run cap 100% duty cycle. Only the run caps make good crossover (Or AC coupling) caps although their size limits their applications mainly to speakers although I do have a circuit similar to this one by Dallas Lankford only using coil values (Crossover coils oversized that I took windings off of until I reach the desired inductance) tweaked to work with available start cap values. Mine will work on any amp up to 50 watts, you just plug it into a Speaker Out and then plug an external speaker into the filter.

8413. Large loop polarization

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-01 15:30:16 UTC
From: Brian Burns
Topic: 8406 Message: 8413

Hello All,

If you feed a large vertical rectangular loop at the center of a side leg, you get vertical polarization. If you feed it at the center of its bottom leg, you get horizontal polarization. It would seem that feeding it at some intermediate point (a corner?) would give you some of each polarization. But, as Gilbert and Sullivan wrote in HMS Pinafore, "Things are seldom what they seem".

The reason that this is an interesting question is that receiving fade, and perhaps transmitting fade as well, are supposedly caused by the ionosphere's messing around with polarization during skip. Claims are that the Carolina Windom succeeds as an antenna because it has some of both polarizations, and limits fade.

Whaddaya think?

Cheers,

Brian Burns

While you may indeed have some combination of horizontal and vertical polarity- it is still linear from a vector viewpoint- so let's say it is linear at 45 degrees- i.e. half way between H and V. This does not help with fading because there is still the possibility that the incoming wave will be orthogonal to that 45 degrees. The solution then is to employ circular polarity.

The issue of feeding so that the antenna will have this 45 degree position is complicated by the fact that if broken down into its vector components- i.e. H and V- the takeoff/arrival angle for the vertical components will be different than the H components. The solution then is far from trivial.

Hello Dale,

Thanks for the speedy reply!

I figured that it couldn't be that easy. Can circular polarity be achieved in at least some sort of practical receiving antenna, if not in both transmitting and receiving?

Part of my interest in loops is their low noise pickup-I live in a particularly noisy location.

Cheers,

Brian

Quick googling result:
http://www.bruhns.us/CP_on_HF/CP_on_HF.html
Unfortunately, this approach only works on one band, because a 90 degree phase shift is achieved by a piece of coax (i.e. on one frequency). But it can be done and is said to yield good results.

8417. Unusual 7 inch ferrite bar

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-01 16:10:00 UTC
From: logically_spock
Topic: 8417 Message: 8417

I have an unusual 7 inch ferrite bar with three separate coils on it. Two coils on the ends and one with just a few turns almost dead center on the bar.

I ripped this out of an old Sony muliti-band radio that covered medium wave, marine/weather band (around 4Mhz), AND long wave that went down to about 100Khz.

The bar has three wires - green, gold, and black, coming off the inside of each of the two end coils and what looks like a regular copper or white wire coming off the outside of each of the two end coils on the bar. I also have the circuit board that these wires are soldered to which has a varactor type tuning cap with a yellow, a black, and a white wire coming off the varactor. I also have a typical MFJ type antenna tuner with switchable coils and a 360pF variable air cap.

I know this isn't going to be easy, but I'm trying to figure out how to hook this up to my Palstar R30CC/and tuner box for some AM and long-wave reception.

This radio is very quiet. With out any antenna hooked up, I tuned it 1340 where a big powerful and troublesome station is (ESPN) and NOT A SOUND! It has both high impeadence/long wire clips and 50 ohm Coax antenna connections.

I hate to throw this thing away and was wondering how I should proceed to try and match and connect this to the radio?

Thanks.

Is it possible that you are confusing MHZ (millions of cycles per second) with KHz (thousands of cycles per second)? If you are trying to build a loop to receive MHz transmissions but plugging KHz figures into formulas, then your calculations will be wildly inaccurate.

As frequencies fall below 500KHz (0.5MHz) the amount of man-made signals reduce. At 1KHz I would expect all signals to be either natural or man-made noise rather than coherent signals. At 1KHz I, personally, would be using audio techniques not radio techniques. At 1MHz, however, I would definitely use radio techniques such as a loop and capacitor.

Don't give up. Let the forum know what signals you are looking for and I am sure you will get help aplenty. If you are definitely looking for VLF signals then there are websites devoted to that pursuit. Take a look at http://www.vlf.it/harald/strangerec.htm or http://abelian.org/vlfrx/ for starters.

Hello Hal,

is that loop vertical or laying flat?
signal in flat position????

It will be a vertically hung rectangular loop, probably a full wave at 80 meters, as that is all I have room for at this narrow end of my property. I’m planning to feed it at the center of the bottom leg, which should give me horizontal polarization.

Cheers,

Brian

If those two end coils are equal in size, I would hook them in series
using the innermost wires first and connect a variable capacitor across the
far ends. Then use the coil in the centre as a coupling loop to go to the
receiver. See how that works, then play with those (assumed) tap wires,
using the same colour of each end and use those for the earlier series
connection. I'd be very interested in learning what you end up with.

The coil on the right end of the bar is equal to the one on the left in size as far as length is concerned, but the windings look like some kind of braiding of wires with I assume, more inductance. I'll try what you say.

Thanks.

That sounds much like what is called a "universal winding", which has the appearance of being braided. Can't recall what the benefits of that form of construction are.

Nostalgic side-note on this topic.

TV and FM broadcasters use what's basically 2 dipoles at 90 deg. fed 90 deg. out of phase to get an omnidirectional reception pattern.

Our local TV station on chan 11 put up the world's first 2000' tower in 1967. To help pay the costs they leased space and shared construction costs with the chan 13 station. Each TV transmitting antenna weighs about 4 tons and with the associated equipment two antennas would have exceeded the safe load limit for a tower that tall.

The Chief Engineer at the time (and my Mentor) Lester Froke designed an antenna and phasing network that would give a good omni pattern on both channels with no crosstalk and SWR that most Hams could only wish for and it was 300# lighter than a commercially produced unit for a single channel.

3 of those antennas were built. The tower collapsed less than a year later when a DC3 clipped one of the guy wires and again in 1975 after a freak ice storm with very high winds. I did get to see the 3rd and final antenna. Looked something like the love-child of a Dalek and a cactus. The fine wires were for static dissipation and according to Les were not on the first unit. I'm still kicking myself for not getting Les to tell me the details of the innards.

At least I got him to reveal the secret of "Franklinizing" an antenna. KELO 1320 still uses the towers he built in the 1950s and as far as I know they're still unmodified from his design. If anyone picks up KELO let me know date/time and I can give you the email of who was on air or on duty at the time for a QSL.

I did some work with VLF/ELF years ago, 60KHz and down to 6.8 Hz. What I found was that below about 20KHz forget about tuned loops. They can be built but to get any directional gain they would have to be huge and heavy. The more wire used the larger the gauge needed to gain any benefit from it. Look up the resistance/Q formulas. Very large capacitors (Relative to RF) and electrolytics don't work very well either because of the low EMF involved. The best results I got were with Tantalum Caps. with a 3V
bias applied.

Other than man-made noise there really isn't much in the 1KHz range other than produced by thunderstorms and Solar flares. From 70 to 200 HZ there's submarine coms. with very slow CW or FSK 5 letter groups, my main interest at the time. 6.8Hz is the resonance of the Earth's magnetic field, vertical with a capacitance hat, or a big loop laying on the ground with low noise audio/instrumentation optimized op-amps with filtering/amplification and you can watch it on a scope but it takes DAYS to see changes in signal.

Then again you could mix the 1KHz signal with a 13KHz then use WinRad......

That Grumpy Old Man..

I want to ask the list members comments about some coax I can scrounge. It is 73506 type which is 6 bundled 75R coaxes. I like that it's double shielded wit both a foil and then a braid over the foil. With the thin sheath over the individual coax and the small 26 ga. center conductor I don't think this would last a real long time outside in the weather, but the price is right, zero, but for my time in the tedious work of splitting and pulling off the outer overall cover of the 6 coaxes. I wonder if this still would make a good low-noise pickup leadin for receive purposes? I had also thought about making a kind of home-made twinax by doubling up these coaxes, with each conductor still double shielded. I don't know if the extra shielding would make a notable decrease in leadin noise pickup in a noisy local environ.

Some of the specs:

The cable has two shielding layers, one of an aluminum-polyester tape, and the other of braided, tinned copper. The exterior insulation layer is typically made of polyvinyl chloride (PVC). The total cross-section of the cable measures from 0.135 inch (for a single coax)....735 coaxial should offer an impedance of 75 Ohms and a capacitance of about 7.7 power factor (pF) per foot from conductor to shield. Nominal signal delay should be around 1.34 nanoseconds per foot. There should be a 30 decibels (dB) minimum structural return loss at signal frequencies between 15 and 95 megahertz (MHz). It should have a maximum operating voltage of 300 volts root mean square (RMS). It should have a maximum pulling tension of about 50 lbs.

(The "power factor" item is copied direct from the website...not my mistake, ha ha! For non-USA readers, "scrounge" = find something usable for low cost or free, especially of something discarded or junked, or from another purpose!)

I have a ferrite rod from a grundig YB700 with windings
of similar make-up you describe.one end coil is the
MW coil ,~240uH,the other end coil is the LW coil,~3mH,
and the center coil,of 4 turns is for an external antenna
connection.This is a very common arrangement.

Main problem with CATV type cables is that some are made with copper clad steel center conductor. These have greater loss at low frequencies (below a MHz or so) than cables with solid copper center conductor. They also have greater DC resistance which can be a concern if powering a remote amplifier over the coax cable.

That being said, the increased loss isn't that great and the cable is certainly usable.

You can actually see an "earth resonance" signal?

What causes it?

What changes did you see in it - freq?

Well, this is from the description: The central conductor of type 735 coaxial is solid copper coated with silver... So that's not an issue.
One strange thing tho, when the outer bundle sheath is pulled off, the
coax gives off a pretty strong "chemical" smell which is very unpleasant and i seem to remember it maybe even making me feel unwell
but i don't know for sure, maybe it was just a long day. -Hue

Yes, there is a weak signal at 7.83 Hz that's caused by the resonance of the Earth's magnetic field. It's been a while since I've done any reading on it but if I recall it's thought to be powered by the Solar Wind. Some New-Age types refer to it as "Gaia's Heartbeat" and I recall seeing portable recievers marketed to the "Earth Change" people in the 1990s. I see the 2012 true believers have decided to adopt it as a sign now too, not to mention the Zero point energy protagonists.

I misremembered the exact frequency, I thought it was 6.8 so I looked it up. Hey, after 20+ years a 1Hz drift isn't bad for an old analog unit like myself ;) It's called the "Schumann Resonance" if you want to read up on it on the WWW. Note that most of the search results point to what I consider Kook-n-Quack sites. PDF from Scientific source <http://www.hese-project.org/hese-uk/en/papers/schlegel_schumann.pdf> is the best I found on a quick search.

Submarine coms use multiples of that resonance, I think the FSK I picked up was the 11th and 13th harmonics. Kinda like coupling to a spherical resonance cavity at odd multiples

I wasn't paying much attention to any frequency shift but the amplitude varied over about a 2:1 range over a 2 or 3 month period. Never looked into it as far as being affected by Solar storms or flux density. It's not something I spent a lot of time on, just wanted to see if I could pick up EMF at that low a frequency, there was no attempt made at calibration and things like dew on the ground may have affected my measurements.

I recall seeing something about local disturbances in the signal right before earthquakes and the harmonics used for lightning detection, there may be other applications.

Sounds like cable for 3 full duplex DS3 circuits which has a maximum clock rate of 45MHz on the line. I see similar cable as this in mobile and "wireline" phone company offices. Much of this is being replaced by high density fiber transports and electronic switches (vs. manual patch panels).

Would probably work well for receivers.The double shielding around a single conductor and the lack of a (predefined) twist between pairs would not make this a good candidate for twinax cable.

OK I made a mistake, there's actually four coils total. I had it taped to the pc board and the taped covered up one of the inner coils.

It looks like the two outer coils are for MW and LW with two lesser turn coils in the center. All are about evenly spaced. The two center coils have a common black wire connected end to end, I assume a common ground.

There was a double black and white wire coming out the back of the radio for an external antenna connect I assume. And there's a black and white wire connected to the ends of the center pick up coil on the right. That must be pick up for a external antenna?

The other center pick up coil on the left next to what looks like the MW wrapping has a blue wire coming off and that common black wire connected to the other pick up coil on the right (common ground).

Now coming off the *inside* of both of the two outer(MW-LW)coils are three wires - gold, green, and black going to the pc board. This is what has me confused. Why three wires? Is there some kind of center-tap here?

Thanks, Gary.

A picture's worth a thousand words:
I created a photo album "Gary's Pics" and stuck a photo of the Ferrite antenna sitting inside a cigar box.

Yes, that certainly does help. It's somewhat obvious from that photo that the windings at the rod ends are not identical, but that might not prevent you from connecting the two together as I suggested earlier. However, those two windings and the tuning capacitor probably should not be connected to ground at any point.

I need an antenna for some MW/AM DXing but also need one with a deep null off the backside. I was listening for some DX but had trouble with stations 180 degrees from the ones I wanted to hear. I'm thinking maybe a flag or pennant with a nice preamp but would also like to hear about any other options. Needs to fit within the backyard. Thanks - John M

Hi John,
I use a 1/2 sized rotatable Flag with a balanced input preamp- I typically see 16-24dB nulls off the rear on AM broadcast. The Flag is 6.5' X 13' from memory. Half sized flag has the same RDF as a full sized- just lower gain.

Hi xtemporize,

If the metal foil is on the outside of the film, next to the braid, it should be OK. Did I get thet right, its a metal foil on plastic film ?

But if the foil is on the inside of the film, next to the dielectric, there is usually some loss asociated with the connector connection. As there is no direct DC path from the braid (which is attached to the connector) and the ID of the film/foil.

The odd smell could be chemical termite proofing which was fairly common back in the 60s and 70s, but I believe it was withdrawn from use in the UK at least, for reasons of health and safety (to humans !). Mike G4HOL

From: Ken
Topic: 8442 Message: 8442

I have uploaded my finished 30m-10m small transmitting loop project to the files section "wa4mnt transmitting loop antenna project". It also can be viewed at http://www.qrpbuilder.com/downloads/loop%20antenna%20110310.pdf . I have been very impressed with the performance, and it has given me the opportunity to work many other bands for which I had no antennas. I continue to amazed at the overlooked potential of these devices. I'll be taking it north to Canada this summer as my only antenna, and hope to get in some good contacts.

I do some chassis design work for Doug Hendricks of Hendricks QRP Kits, and I was fortunate enough to get to build up one of the beta versions of Steve Weber's (KD1JV) Deluxe Tenna Dipper kit. I find it great to find the resonant spot tuning my small magnetic loop without using a transmitter. It covers 80m - 10m, and you set your frequency on the digital readout of the Tenna Dipper that you wish to operate at, and tune the antenna until the led goes out, and you are at resonance. You can really see the sharp dip of a magnetic loop. It's not an interactive looped-back motor driven device, but it sure makes tuning easier on my loop. It's powered by AA's and fits in my shirt pocket.

Hello All,

Well, I'm about googled out. I've been trying to find info on a two turn, single element loop for 40 meters, and no luck so far.

I figure it would be about 1/8th wavelength on a side if square (approx. 17'), and could be rotated to give me some propagation in an easterly direction. With a tilting mast I could lay it down out of sight behind my shop when I'm not on the air. Anyone have any experience with such an animal, or have links to info?

Thanks a bunch,

Brian Burns

A TWO-TURN 40-80 METER STL ANTENNA
Augie "Gus" Hansen, KB0YH

INTRODUCTION

This article describes a two-turn small transmitting/receiving loop (STL) antenna that covers 4080
meters. The article compares and contrasts single-vs. multi-turn loops from design and construction perspectives, and evaluates actual performance via field testing.

Small transmitting/receiving loop antennas, commonly called magnetic loop antennas, have fascinated me ever since I saw one in the late 1970s. It was a one meter wide octagonal copper
loop that had been abandoned after what I was told was a ?short and frustrating period of testing

? OK for receiving but a poor performer on transmit.? At the time the thought of a small antenna appealed to me because my wife and I were renting a home and putting up big antennas
was out of the question. But that loop had been lying on the ground for several years and revealed its age and neglect by heavy oxidation and corroded joints. At the time I opted instead
to hide a multi-band vertical in the back yard. It would be several years and a move into a purchased home before I got back to the task of building my own antennas, including several STL antennas.
Having since built and used a large number of STL antennas for the ham bands in the 10-54MHz
range, I know how effective such small antennas can be if designed and constructed correctly.
STL antennas have been an integral part of my modest antenna farm, ARRL Field Day activities,
and emergency ?go? kit for more than 20 years. Several years ago at the urging of my friend Don, W0ZN (X-KB2Z, and now SK), I undertook the task of building some STL antennas for use on the lower frequency bands. Although there are no significant antenna restrictions at my
current location, several of my ham friends suffer oppressive antenna restrictions and need something small and effective for 40-160 meters. I'll address the 80-160 meter STL that I have
been field testing during the 2008-2009 Winter season in a future article. This article focuses on a
4.5-foot (1.37m) diameter, two-turn STL for 40-80 meters that can be easily hidden in a yard
(garden) or an unoccupied interior space such as an attic or garage.

ONE GOOD TURN DESERVES ANOTHER

Until about a year ago my STL antennas were all single-turn types, none larger than two meters
in diameter. Compared to a single-turn STL, using two turns for the same loop conductor length
shrinks the antenna size dramatically without significant reduction in performance. Photo

1
shows a single-turn STL that is about nine feet (2.75 meters) in diameter that covers 40-80 meters with a suitably large tuning capacitor. In this design, with the loop supported vertically,
the feed point is at the bottom of the loop opposite the gap at the top where the tuning capacitor
is located. This test antenna was manually tuned, so a tall ladder was used to reach the tuning
capacitor while observing the VSWR on an MFJ-269 Antenna Analyzer.

Photo 1: A one-turn STL that covers 40-80 meters.

Photo 2 shows the two-turn version of an antenna that covers the same set of bands, but is only

4.5 feet (1.37 meters) in diameter. Note that the feed point and the tuning capacitor are both at
the bottom of the loop. The feed point and the tuning capacitor are still electrically 180 degrees
apart, but physically adjacent. This arrangement simplifies hanging the antenna from above. If
the antenna is supported by a post or pole from below, the feed point and capacitor could be
positioned at the top instead.
For its intended use the antenna had to be small and easily constructed in an attic that is accessible only via a small hatch that is 2 feet square. That requirement alone meant that the
antenna had to be brought into the attic in pieces and assembled in place. A piece of scrap Heliax
for the conductor and a PVC frame nicely met the in situ assembly challenge. The remaining components include a coupling loop and a remotely controlled tuning capacitor, each small enough to easily pass through the hatch.

Photo 2: Another version of the 40-80 meter STL that uses the same loop conductor length, but formed into a two-turn wide-spaced coil.

For tuning the loop I have used both air-variable and vacuum variable capacitors, the choice
determined by the intended power level. A good air variable capacitor of either split-stator or
butterfly construction can easily handle up to 200 watts if correctly sized (wide plate spacing)
and welded to minimize losses. A vacuum variable capacitor with 15KV and 60 ampere ratings can handle up to about 500 watts.

BANDWIDTH VALUES

There are differing types of bandwidth to consider when describing STL antennas. The instantaneous bandwidth for transmitting can be taken to mean the frequency range over which the VSWR is 2:1 or less. Some transmitters, especially those that uses tube (valve) finals, can output full power within this limit. However, most modern transmitters automatically reduce power output when the VSWR rises above a predetermined safe value, often as low as 1.5:1 or so. Using an Icom IC-765 transceiver at minimum power (about 10 watts) for the VSWR tests there was no measured power cut back until the VSWR exceeded 5:1.

The instantaneous bandwidth for receiving is generally taken to mean the 3dB (half-power) bandwidth. It correlates to a slightly wider range of frequencies as determined by about a 2.6:1 VSWR bandwidth. It is critical that the VSWR obtained at resonance be 1:1 so that the high and low 3dB frequencies can be determined accurately and the difference calculated. Then the antenna Q can be calculated as the center (near resonant) frequency divided by the difference. In practice the transmit bandwidth is slightly better than one third the receive bandwidth.

Operational bandwidth is a term that describes the useful range over which the antenna can be tuned and used successfully. In my view this range leads to a loop perimeter from 0.1 wavelength at the low-frequency end of the range to 0.3 wavelength at the high-frequency end. Loops with a perimeter shorter than 0.1 wavelength exhibit very narrow instantaneous bandwidths that can't pass SSB signals with full fidelity, never mind AM or FM. Those having a perimeter longer than 1/3 wavelength do not qualify as small. According to John Kraus [KRAUS] the condition of constant loop current is met to within 1% for a perimeter length of 1/3 wavelength. In addition, small loops become self-resonant near this length given the values of loop inductance and stray capacitance. Therefore, I use a high-frequency perimeter length goal of 0.3 wavelength in my designs to provide some margin.

Tuning range is the range of frequencies over which a given loop conductor can be tuned by a given capacitor. A large maximum capacitor value can be used to resonate the loop well below the low frequency end of the operational bandwidth, but the loop efficiency would be very low. Also, the instantaneous bandwidth becomes impractically narrow. In effect the extra range obtainable by using larger-than-necessary capacitance values would be ineffective and wasteful in a practical STL design. As a practical matter, I use what is available that covers the desired range at reasonable cost.

MATERIAL AND COMPONENT SELECTION

The loop conductor for this 40-80 meter STL is made from recycled 7/8-inch hard line. Only the outer surface of the copper shield is used, so you can use any sufficiently long piece, such as ?cut-ends? or ?pulls? that can be obtained inexpensively or even for free from cable and wireless companies. I prefer this type of loop conductor because it is continuous, is protected from environmental elements by a sheath, and is fairly light weight. The lightest hard line seems to be the type that has foamed insulation and a tubular center conductor. Some hard line uses a plastic spiral wrap to support a solid rod center conductor (typically copper-coated aluminum) inside the shield, providing an air dielectric. This type tends to be a bit heavier. Either will work well electrically, but the lighter hard line makes STLs that are easier to handle.

The end cap treatment that I use for my loops makes it possible to have low-loss connections to the tuning capacitor without having to solder or weld directly to the capacitor. As long as the connections are tight and have large enough surface areas the resulting antenna will have low loss resistance (assuming the capacitor itself has low series resistance).

Photo 3 shows the end treatment of the loop conductor. It consists of a short copper tube secured to the hard-line shield mechanically with several brass screws, and then electrically with silver-bearing solder. Use rosin core solder, not acid core for this purpose. The overlap is about 4-6 inches, which is enough to provide stress relief and crush resistance for the hard-line shield at the attachment points, where some form of clamping is usually needed. A copper end cap is fitted with a 3/8-inch diameter, 1-1/2-inch long brass bolt, brass lock washers inside and out and a brass nut. These components are soldered both inside and outside the end cap before it is soldered to the short copper tube. A pair of brass flat washers and a stainless steel lock nut for securing jumpers or capacitor leads complete the assembly.

Photo 3: The loop conductor end treatment provides weather protection and a way to make solid electrical connections.

After the end assemblies cool to near ambient temperature, to protect the copper surfaces and preclude water entrainment between the hard-line shield and the plastic sheath, I apply a layer of

coax seal or equivalent followed by several layers of vinyl tape or heat shrink tubing.

antenneX Issue No. 145 ? May 2009 Page 5

The loop frame is made of structural PVC tubes and connectors, elbows, and end caps. This material is UV protected and is typically used to construct patio furniture and storage racks. I
purchased my PVC parts at a local hardware store. It is also available from several on-line vendors, for example ACF Greenhouses (
http://www.littlegreenhouse.com/accessory/pvc.shtml).
Do an on-line search for ?structural PVC? for a list of vendors. I use screws to hold the pieces
together rather than PVC cement because the parts are often reused for other antenna experiments. For initial testing my loops are usually suspended from a tree branch using a pulley
system, hence the eye-hook at the top of the loop. This technique facilitates testing the antennas
at various heights above ground.

To obtain test data that is not adversely affected by losses in the tuning capacitor I use a vacuum
variable capacitor (VVC). In addition to offering very low loss a VVC provides excellent immunity to environmental factors. Other capacitors that I have used in the past, such as air
variables and homemade trombone-style capacitors, suffer from drift caused by temperature variations and peak voltage reduction due to high humidity. VVCs also can provide low minimum and high maximum capacity values in rather small packages. They're expensive, but well worth the cost in the long run.

Photo 4: The vacuum variable capacitor is remotely controlled over the coax. A 12-volt DC gear-head motor and belt/pulley system provide satisfactory tuning rates.

antenneX Issue No. 145 ? May 2009 Page 6

The tuning unit pictured in Photo 4 consists of a VVC controlled by a surplus 30 RPM gear-head
DC motor and belt/pulley system. A set of micro-switches limit travel to prevent damage to the
capacitor at the tuning extremes. NOTE: This tuning unit provides smooth tuning over the range
of about 5-9 MHz using a 6-110 pF VVC, a Jennings UCSV-110-15S. The tuning unit that permits coverage down to about 3 MHz with this two-turn loop uses a 12-500 pF VVC, a Jennings CSVF-500-0315. It is being used with a three-turn STL for 80-160 meters that is under
test at the time of this writing. My source for vacuum variable capacitors is Max-Gain Systems,
Inc. (MGS, http://www.mgs4u.com). The pulley and belt components were obtained from Small Parts (http://www.smallparts.com/). I had to drill and tap the pulleys and add set screws to obtain
sufficient holding force. They are ?pressure fit? pulleys as supplied. The micro switches were
obtained from a model train hobby shop. They are very small and called ?power directors?,

with
extension arms that can be bent to provide easy adjustment of the limit points. A small plastic
block, tapped and drilled to slide freely on a threaded plastic rod, provides the activator for the
limit switches (normally closed) and reverse diodes provide the current path when the tuning
direction is initially reversed after having reached a limit.

The shack end of the feed line has a control unit that is simply a variable voltage power supply
(3-12 volts DC) with a momentary DPDT-center-off switch. 12 volts provides a reasonably fast
slewing rate for band-to-band movement and 3 volts provides a fine-tuning rate. Each end of the
feed line has a DC blocking capacitor of 0.1 uF at 2 KV in series to the connected device (rig,
antenna) and a 100 uH inductor to block RF and provide the DC path for the motor control
voltage. Articles published in antenneX and elsewhere show several remote control systems
including some interesting auto tuners that work over the coax feed line.

FEED SYSTEM CONSIDERATIONS

Because the loop conductor is coated (PVC jacket), the most practical method of driving the loop
is via a separate coupling loop. The other often used method is an autotransformer, but this
method would require exposing portions of the conductor surface to facilitate adjustment of the
tap point, inviting problems caused by surface oxidation and possible water entrainment.

The primary factors that affect the success of this method are the relative sizes the loops, the
position and shape of the coupling loop, and the proximity of the antenna to other objects and RF
ground with which the coupling loop interacts. My tests of multi-turn STLs show that the
impedance transformation is a function of the relative areas of the coupling loop and the main
loop regardless of the number of turns. The recommended 1:5 ratio of loop diameters for single-
turn loops is a reasonable starting point for multi-turn loops as well.

The treatment of small transmitting loop antennas in the ARRL Antenna Book [ARRL] gives an
approximation of the radiation resistance as being proportional to the square of the product of the
number of turns and the loop area. Because the overall loop conductor length is the same for both
the one-and two-turn loops, there is no increase in radiation resistance. Indeed, it is cut in half
when going from one turn to two turns, emphasizing the need for high quality components
(conductor and capacitor) and connections.

Much has been made of the purported noise suppression characteristics of shielded loops. I haven't found the extra effort to build them justifiable. The primary benefit is actually a reduction

of feed line radiation, but only if the loop structures can be made well balanced, which is usually
difficult in practice. You can see in Photo 1 that the one-turn antenna uses a simple insulated
wire (#10 AWG) for its coupling loop, with a line isolator (choke) at the feed point. Without the
choke there was a small but detectable current on the feed line. The two-turn loop is driven by a
balanced shielded coupling loop. Balance is good enough that little or no current can be detected
on the coax feed line.

MEASUREMENTS

To assess the quality and performance of an STL the first order of business is a transmit bandwidth test. A check of the 2:1 VSWR is a good indication of the health of the antenna because it reveals antenna losses, with lower loss values resulting in narrower bandwidths. If test
results reveal a broader than expected bandwidth, this is a sure sign that there are excessive
losses in the system. Such losses are usually caused by bad connections, the use of poor quality
components (loop conductor and/or capacitor), and RF absorbing objects in the near field of the
antenna.

With the two-turn STL suspended about two meters above physical ground as measured to the bottom of the loop, the transmit bandwidth values on 40 and 80 meters were obtained and compared to expected values. I used values predicted by magloop4, an excellent program written by R. J. Edwards, G4FGQ. It deals with only single-turn loops, but provides a reasonable
guide to expected values. (I will attempt to write a program that works for multi-turn loops after
collecting additional experimental data.) On 40 meters the instantaneous bandwidth was measured as 11 kHz, which is a little bit wider than the predicted 9 kHz. This indicates some
losses in the system, most likely in the short #6 AWG jumper wires and connections to the vacuum variable capacitor, plus some possible interaction between loop turns. Similarly, on 80
meters the bandwidth was approximately 3.6 kHz versus the predicted value of 2.5 kHz. (These
measurements were made with the 500 pF VVC installed.)

To make meaningful field strength and pattern measurements, the loops will need to be taken out
to a suitable test range. However, the relative signal strengths and patterns for the multi-turn and

one-turn STLs have been nearly identical when measured at one mile from my back yard location. On-air performance of both loops has been quite acceptable when compared to other antennas, such as inverted vees and verticals, in both contests and occasional casual operation
over a period of six months

CONCLUSIONS

A multi-turn STL antenna provides acceptable performance in a small package. It was well worth
the effort to build the two-turn STL for 40-80 meters described in this article. I have been
convinced by the experience that similar STLs with even more turns can be effective on 160 meters, permitting radio operators with limited space and/or legal antenna restrictions to have fun
on the low-frequency bands. -30

8449. Does shape matters?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-14 20:41:23 UTC
From: vaclav_sal
Topic: 8449 Message: 8449

I am busy copying Ken's WA4MNT transmitting antenna design and bugging him with silly questions.
So I decided to bug y'all for a change.

Found very math oriented article on small loop where the author repeatedly states that "the shape does not matter (in far field)".
So - I am trying to find a compromise between expensive ½ inch soft copper tubing, mechanical rigidity (what a awful word) and lowest possible resistance (minimal number of solder joints).

I am "leaning " towards 3/4 or 1 inch "hard " copper in rectangular shape.
I think "standard" copper pipe comes in 10 ft or 6 ft.
I feel ½ inch would be too flimsy if soldered. (Anybody remember Ike ☐ I want this to be an outdoor antenna in Texas)

Now for the questions.:
Would square (1:1) shape be mechanically preferable?
How far can I "squish" the vertical sides.
How would it affect upper frequency (30 MHz desired)?

Would I face a challenge forming the "pickup" loop - can it still be circular?

Years ago I used some magic liquid (chemistry was my least favorable subject) to put silver on PCB traces. I wonder if anybody ever used it on small loop copper stuff. If I recall , it would tarnish quickly, and that was using it indoor.

Thanks for reading

Hello vaclav_sal,
On my loop adventures and experimentation I've found the loops aperture is a direct function of the available efficiency. Otherwise I would of ended up with a loop like a dipole made from twin feed capacitively shortened to frequency.

If its big or you have issues with bending then make it octagonal or square. Don't worry too much about out and out efficiency unless its too small. I would have the feed on a 90 and the cap on the opposite end. Good way to find centre and give close coupling to the coax.

If you can have the joints brazed (silver soldered) then it will be as good as continuous.

Where possible. I kept the current end where I required most transmission strength. Never had the Feed at the bottom.

My loops have been
22mm on a 3m length
10mm over 6 m length
3x3m lengths on 22mm
Assume 22mm OD is 3/4" and 100mm as 1/2"?

My upper frequency limit has always been no more than 1/3 wavelength which is its most efficient size but not tightest bandwidth.

I've only been happy matching with a Faraday loop and best placed mounted in a triangle shape opposite the tuning cap onto the major current point where the coax feeds to; gives best signal.

If you have an air spaced cap. It's good to have the vanes balanced to 0V. ie. twin gang. So touching it to tune, weather etc. will not affect it.

I've always rough tuned the loop visually by having a few turns of wire with an LED soldered to the ends. Put out say, 5W and tune up until you get the best glow. Its strapped to the loop. After fine tuning, I've had no issues with the LED on 100W.

I have considered making a (deaf) pll to sense voltage and current phase to auto tune the loop.. Anyone done this? here's my inspiration:
http://www.carc.org.uk/pdf/Archive_010.pdf

All the best guys. May the noise never be with you.
Andy.

For what it's worth, most things I've read say that shape doesn't matter MUCH ... but it can.

I think the objective is area, so squashing a loop so that it is a flat rectangle with no area, definitely hurts.

But once you get close to a square (maybe even a triangle), the differences between one shape and another, with roughly the same enclosed area, become minor. Hence, reasonably open rectangles are OK if that's the available space you have to work within.

> Years ago I used some magic liquid (chemistry was my least
> favorable subject) to put silver on PCB traces.

I remember using a powder: "Cool-amp". Neat stuff. You'd clean the PCB, wet it, sprinkle on the powder, rub it in, and wipe clean. It seemed like magic.

> I wonder if anybody ever used it on small loop copper stuff. If I
> recall , it would tarnish quickly, and that was using it indoor.

A friend at a radio station where I worked ... also where we made PC boards and plated them with this powder ... tried using it on a coaxial low-pass filter on the output of the FM transmitter. The unexpected result was a lot of arcing, causing pops, drop-outs, and shutdowns for the next few months.

He guessed that maybe the plating had increased the Q or something.

About the tarnish: Silver does tarnish, and so does copper. As I recall, we found that the silver-plated boards tarnished less, which is why we used the stuff. YMMV.

Andy

8452. Small Shielded Loop Antenna - Inside the Shielded Metal Box . . .

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-16 14:06:56 UTC
From: Ralph
Topic: 8452 Message: 8452

Question:

Joe Carr's diagrams in this Forum's Antenna Toolkit shows the coax loop's center conductor coming to a metal box, on both sides, with the shield joining the metal box body on both sides. Within the box, the center conductor on both sides runs thru a variable capacitor. If I am understanding the schematic correctly, this means one end of the loop connects to one of the 365 pfd variable cap's solder lugs while the other connects to the v-cap's body (ground). Then, a connection with the center conductor (non-grounded side) runs to the receiver.

Question: why doesn't this antenna just ground out? Am I understanding the set-up correctly?

If someone can confirm my understanding, or else can correct my understanding in clear instructions, would be much appreciated!

If you post this question again, you might want to include a link to
the book along with the page number and illustration figure.

8454. Ferrite rod transmitting antenna for 40m QRP CW?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-17 00:40:45 UTC
From: qrp.gaijin
Topic: 8454 Message: 8454

Hello people,

I just found this group and have had an interest in loop antennas for some time. I'm studying for my amateur radio license and would like to use a small transmitting loop for QRP CW use on 7MHz and higher frequencies, with output power between 1W and 10W. I'm already using a coax loop for receive on my homebrew regenerative receiver, with good results.

My question is: can a ferrite rod antenna (also called a loopstick - the kind you see in AM radios) be used effectively as a transmitting antenna at 7MHz with QRP power levels?

I saw a very intriguing design for a transmitting ferrite rod antenna for 3.5MHz here: http://www.zs6wr.co.za/anode/AnodeSeptember2009.pdf . I was wondering if anyone here has experience with this kind of antenna for transmitting. I think it would be nothing short of incredible if a tiny, lightweight, ferrite bar antenna could be used as an efficient QRP antenna, and perhaps even work some DX if propagation is good. Could efficiency of a ferrite rod antenna approach that of a traditional, larger magnetic loop antenna made of copper tubing?

Thanks for any comments or insight. I've raised this question in other forums with little response, so I'm glad I found this group dedicated to these interesting loop antennas.

Figure 9.11 - Yes the center conductor is connected to ground. However, you will have to think of grounds two ways, AC/RF grounds and DC grounds. DC grounds are what appear as a short circuit if you were to connect a battery to the coax. This is exactly what is shown in the Figure. From an AC perspective, however, the loop is part of a resonant structure (coil/inductance) which is tuned to a range of resonant frequencies with the variable capacitor. There is some interplay between the antenna and the fact that the center conductor is routed to ground. A variation would be to use a small value variable capacitor in place of the capacitor/center conductor to ground connection to decouple the shield from the antenna.

It would be interesting to see such a design made available. In the meantime, here's a simpler and less expensive approach to a transmitting loop for 40M:

http://www.home.earthlink.net/~christrask/Paper012.html

It does away with the typical vacuum variable capacitor and/or Faraday coupling look, and reduces the mechanical complexity.

Am downsizing some items and I have an AOR LA-320 Loop Antenna with three loops.....(1) 320M covering .540---1.6 Mhz.....(2) 320S covering 1.6---5.0 Mhz.....(3) 320 H covering 5.0---15.0 Mhz. The unit is in perfect cosmetic and electrical condition. Works great! Included is AOR connecting cable and new 9 Volt battery. Photograph available. $225.00 Postal Money Order. Shipping charges to lower 48 included.

8459. Pixel Technologies Magnetic Loop RF PRO 1A

New member here.

Does anyone have experience with the Pixel Technologies Magnetic Loop RF PRO 1A?

I'd appreciate comments or thoughts about the antenna specifically focused on its use in the LF and VLF range. I am presently using an active whip antenna, but the ever rising urban noise level has me looking at other alternatives.

Thanks,

Scott

Hi Scott :

I have had this loop for about 8 months ,I'll try to help if i can however i dont DX LW,and im not sure what you meen by VLF?

I use mine for AM and SW Dxing ,i do know i can hear several beacons on LW with it ,stations i never heard before getting the loop.

What i can do is record a station if you like,or several, and send you a clip ,if that helps?

Let me know

Whatever you guys discuss about this loop, the company (Pixel Technologies) is remiss in their business practices, trying to scalp their customers for inflated "shipping and handling" charges much as the shysters on late-night UHF TV used to do.

When I attempted to order one of these tonight, they tried to charge me $24.00 shipping (to Indiana) which is somewhat outrageous. Then, without my prior consent, they tried to charge me an additional $14.00 "shipping and handling" on the PayPal page. Doesn't seem very honest to me.

That's not all they scalp. Months ago the owner of Pixel approached me, wanting me to design an amplifier for them so that they could compete with Welbrook. I sent them information betond what they already had, and then they never returned any emails. So, I designed the amplifier and published it online (it's in the group files section). Now anybody can make one, and it beats both Pixel and Welbrook.

Excellent Chris- these prices are outrageous.
And if you believe their hype- these loops are close to magical.
I recently had the opportunity to run some tests on the Wellbrook vs my homebrew shielded loop with preamp. No net S/N difference, and my loop always had as good or better nulls.

I have to give them credit for being the first to use the Meobius Strip
Loop in a commercial product. Good use of an interesting innovation in
antenna design,

Here's the formal definitions of the frequency band divisions.

HF = 3-30 KHz
MF = 300 kHz - 3 MHz
LF = 30 kHz - 300 kHz
VLF = 3 kHz - 30 kHz

8470. Phase Relationship of Loop and Sense Antennas

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-19 03:55:14 UTC
From: Greg Ella
Topic: 8470 Message: 8470

Am I correct that with a small magnetic receiving loop antenna, vertically oriented and with the edge pointed towards a distant vertically polarized transmission source, and with a vertical whip sense antenna next to this loop, there will be a 90 degree phase difference between the induced voltage in the loop antenna and the induced voltage in the whip antenna?

Furthermore, is it then necessary to shift this phase difference an additional 90 degrees in a loop and sense direction finding system, so that when combining the two signals they cancel out with the loop in one direction, and add when the loop is spun around 180 degrees in the other direction?

Greg Ella,

Livermore, Ca

Subject: [loopantennas] AOR LA-320 Loop Antenna

Am downsizing some items and I have an AOR LA-320 Loop Antenna with three loops.....(1) 320M covering .540---1.6 Mhz.....(2) 320S covering 1.6---5.0 Mhz.....(3) 320 H covering 5.0---15.0 Mhz. The unit is in perfect cosmetic and electrical condition. Works great! Included is AOR connecting cable and new 9 Volt battery. Photograph available. $225.00 Postal Money Order. Shipping charges to lower 48 included.

Hello Chris,
That is the way to treat companies like that.
Would have been better if you could make a few coins also, but I do
appreciate you posting it in the files.
Keep up the good work,
I get over my head on some of your things but come to the surface with a
little research for the most part.

I received an E-mail last night regarding Pixel Technologies shipping charges. Apparently, they had made an honest mistake on PayPal which caused the additional shipping charge to be added onto the $24.00 FedEx charge. Apparently, they are new to PayPal and inadvertantly "hit the wrong button". They have now corrected this and graciously sent me an apology.

From: John
Topic: 8459 Message: 8478

Just to remind the other folks here, I ordered the PRO-1a several months ago. It was delivered in a few days with no s/h charges - as agreed. Not everyone is dissatisfied with their service.

It works quite well at 11 ft behind my house on a 5ft mast section mounted to my deck, putting it's loop's center ~8 ft off the ground. With the loop parallel to my house - and the HV lines in front of my house, it nulls the ever present powerline hash and RFI/EMI radiated/reradiated from my home quite well. It is adequately made, mechanically, and seems to be well designed electronically - and works well to 150 kHz. Certainly, my signals from .15-20MHz are much more readable than they are on my random wire antenna running through the back yard. My old 145ft LW - even my TTFD - would be rendered useless from that sporadic powerline EMI. I even fed the TTFD with 450 Ohm ladder line to the house - then a 9:1 BALUN at the window - less noise, but still S7-S8 at times (S9+ at times on the LW antenna - R8 & NRD525). Now it's barely discerned in the background (<S1 - NRD525 & Palstar R30A).

I have a basement full of tools - and some, admittedly dated, test equipment. I got my 1st Class Radiotelephone License in '68 - chiefed for several FM stations over the years, was a USN ET - schooled in the R-390A - from '69-'72, graduated from AU '75 in physics, and taught electronics & telecommunications in AL's post secondary system from '75-'95. I have several metal lathes - and a mini-mill. I have electronic parts - even some PCB material - photo goodies & etchant - raw PCB - and glass epoxy P holed board for pt-pt wiring design tests - and some ferrite/iron Amidon toroids, too. I have built remotely tuned & amplified loops for MW - tropical bands. Heck, my 'ultimate receiver' is still a 40 yr 'work in progress'! Why buy? Simple - I wanted something that worked - fast! I am retired - I have the time to build - but I wanted something 'now'. I got it!

Sure, it was a bundle - I had the money put back for an R75 - but, it wasn't enough - it would buy the loop - so, against my frugal nature, I bought it. 'Second thoughts' fade when I turn the R30A on - and the loop - I just wish we still had the SW broadcasters we once had. Again, not everyone is upset with the PRO-1A - or their s/h.

John

There's also..

ELF = 300Hz-3KHz
SLF = DC-300Hz

The only current uses I'm aware of offhand for ELF is lightning
detection and monitoring some ionospheric phenomena.
SLF was used for submarine communication and magnetospheric monitoring.
Also shows promise for earthquake prediction.

There isn't a single part in that design that cannot be readily
purchased. The transformer cores can be bought from Amidon or W8DIZ
(www.kitsandparts.com).

You cannot link directly to a file or photo in Yahoogroups. It gives you a link that works for 30 minutes at most.

You can link to the Files, or even into a folder. Scroll to the bottom, Chris's PDF is at the bottom:
http://groups.yahoo.com/group/loopantennas/files/

Or you can even add the name of the file manually:
<http://groups.yahoo.com/group/loopantennas/files/WidebandLoopAntennaAmplifierRevA.pdf>

However, spaces break the link. Which is one of the many reasons I don't like spaces in file names and folders. I just removed the spaces from that file name, so it should work.

I can't Google up a way to cross reference Fair-rite cores to
equivalent W8DIZ parts. Can you suggest his equivalents for all the cores?

BTW, I don't see any spec for the core of L1. What core does it use?

Thanks

:how far away from the loop should i install the vertical to keep the 2 from mutual coupling ?
i have heard zero separation is ok but not sure i can do that ,would like to have the optimum setup for phasing ,if there is such a thing?

Also does cable length (of a loop and vertical)have anything to do with phase?

P.S.
I have been using the loop phased against a BOG (120 feet aprox.),so far i have been able to get 180 degree phasing ,but have not been able to kill my local,i think my shack is just too close to it ,Rf saturation .

Thanks

Nothing is specified for that part as it is optional and depends on the
users requirements.

The transformer cores can be bought from Amidon or W8DIZ
(www.kitsandparts.com).

Mouser is a good place to look for the other parts.

Jerry, copy and paste the link to a text file. Then go through it and remove any spaces inserted between characters. I don't know why, but yahoo does this.

Then copy that repaired url and paste into your browser. Voila!

Paul

Hello Vasile,
I am confused (does not take much these days as I am in my eightieth year) I am looking for a 25 pf variable capacitor with a minimum of 2mm (0.08") between plates and preferably with a remote motor drive coupled to it. I am attempting t build 80 meter frame antenna by SM0VPO.
If you have please quote price. Your help in his matter will be sincerely appreciated.
Cheers

Despite carrying my measuring caliper to the hardware store I run in to small problem with my new transmitting loop. Apparently soft copper ½ inch flexible line OUTSIDE dimension is not same as M type pipe of ½ inch size, again outside dimension, because my ½ inch to ¾ tee connection flops around with large gap. I did not measure it ☐ the fact is it cannot be reasonably filled with solder.
I am using the tee to connect the main loop to the piston style capacitor.
So I need to fill this large gap .
I am thinking of using the standard 3/8 end cap as reduction device, it fills the flop gap but obviously requires double soldering which I would like to avoid.
I guess the question is ☐ can the flexible soft copper pipe be enlarged so it will fit into the tee ½ side snugly. And does that have to be done by an experienced plumber's tools ?
Any other constructive suggestions are as always appreciated ,
Thanks for reading

I use thin-wall brass tubing to fill the gap. You can also use brass
shim stock, wrapping it around as you would tape to build up the needed
diameter.

>

You could use a flaring tool, but I would try the brass tubing or shim
stock first. Spreading a little flux on the shim stock as you roll it on
will help get a better joint.

73 Vaclav AA7EJ

Hi Vaclav,
I believe the actual O.D. of flexible copper tubing is the same as the size
listing. So 1/2 inch
soft copper or refrigeration tubing is exactly 1/2 inch or 0.5 inch O.D.

The O.D. of rigid tubing is usually 1/8 inch larger than the size listing,
so 3/4 inch hard copper
tubing is actually 7/8 inch O.D.

All adapters are sized for rigid tubing, so you would need to find an
adapter for 3/8 inch to 3/4 inch
rigid tubing. The O.D. of 3/8 inch rigid tubing is actually 1/2 inch so an
adapter for 3/8 inch rigid
tubing will fit the O.D. of 1/2 refrigeration tubing.

If you can't find what you need locally there are a number of online stores
that sell adapters in all sizes and they should have what you need. I
think that would be a better solution than trying to enlarge 1/2 inch
soft copper tubing.

Thanks for replies.
I suppose there would be no harm done to use tape or tubing to provide mechanical connection about 3/4 way in , soldered, and fill the last 1/4 (or less) gap with silver solder.

I'll check on the flaring tool with local hams / plumbers.

Vaclav

If you have any extra tubing cut two 1/2in sections and split them lengthwise and use them as shims to fill the gap.

For refrigeration copper we use a swaging tool, I use a pro version that's a lot like a flaring tool
http://www.amazon.com/Yellow-Jacket-60440-Swage-complete/dp/B003ANRLHO/ref=pd_sim_sbs_hi_8
but you can also get a cheaper version that's something like this
http://www.google.com/products/catalog?oe=utf-8&client=firefox-a&q=swaging+tool&cid=6959058365348049744&ei=tOW1TeyDLJCMNfuWzbkL&sa=image&ved=0CBEQ8gI#

We use this in place of couplings which saves one solder joint because silver brazing rod isn't cheap and the fewer the solder joints the less potential for leaks

Things that I've done in a pinch is use an old deep well socket, getting the right size can be hit and miss though. You use it like the cheap swaging tool by beating it in with a hammer

Personally I'd just get out a stick of Silver brazing rod which will fill a gap and still be stronger than the copper pipe itself. If you know someone who does refrigeration or A/C work they might be able to get you a couple of old 2-3" ends, I know a lot of guys just toss them when they get that short. In fact I put in my entire new system in 2008 using nothing but short pieces of silver rod that I found around rooftop units. You need a good hot torch (like a Turbo Torch brand) to use it though

I make most of my loops out of 'soft' refrigeration copper because I get old scraps for free and it's a lot more rigid that soft waterline copper. Be aware though that the fittings and pipe are all sized by OD not ID like water pipe.

Hi,
In the pipeshop at the factory where I worked they used tapered boxwood versions
for copper / lead, up to fancy ones incorporating roller bearings for steel pipes.

Thanks for all the advice.
I guess I need to hookup with local AC shop, should not be a big problem in Houston.I'll try the swaggering method, but I am affraid to damage the pipe in wise.

I am not trying to split hair - but can I mix "regular" solder with silver?
Anyway, I think putting the regular 3/8 cap on the end and soldering it on with regular solder and than solder the capped end into the tee with silver. If I fill the gap all the eay to the pipe surface the RF should like it because of the skin effect.
Any comments on that?

By the way I think I found good source of quality insulation (low loss) material - plastic kitchen cutting board. Now if I can make sure it is the real high density poly I'll be happier.

Electric motor from child riding toy - with reduction transmission looks very promising.
And it fits snuggly on top of the camo surplus pole!
The only "problem" with these poles is the odd diameter _ 1 13/16!
It must have a same history as copper pipe sizes HI HI.
Thanks for round files and sanding paper!

Greetings to members,
This is my first post so please bear with me if it does not meet the normal criteria.
I am building the 80 meter Frame Antenna by Harry Lythall SM0VPO. Like all projects I sort of go at them bull headed and have machined a spider hub from 6" diameter aluminum from which I intend to attach 1" square x 1/8" wall aluminum tubes I the machined slots. See attached digi pic. These arms will be suitably drilled at intervals and rubber grommets installed to thread the insulated stranded wire. A friend today raised the question as to should I be using aluminum arm which stopped me in my tracks. My recollection of building quad antennas back in 1974 was that I use aluminum tubing but that the ones I built with fiber glass arms worked better.
So my question to the group is have I made a blunder in making the arms in aluminum????
Today I sold my Butternut HF9 vertical antenna so I am off air until I get something up to replace it.
Your views and recommendations will be sincerely appreciated.

You could probably see the effect of the arms using one of the
antenna modeling programs. Run the design with and without them and
see the differences.

I would not even consider using metal arms for a small loop. It would lower the Q, thus lower the efficiency, modify the resonant frequency and invite arcing. It would be similar to using a metal tube as a coil form!

You could probably see the effect of the arms using one of the
antenna modeling programs. Run the design with and without them and
see the differences.

My gut feeling (based on a bit of loop antenna experience) is that the central metal piece is more detrimental to the loop performance than the radial tubes. It is like a pickup loop, only short-circuited. 6" may not seem like a lot, but it will definitely cause some losses.

Several free ones are available. Google "antenna modeling software".
Takes a bit of study to understand how to use them, but it is well
worth the effort. IIRC, 4nec2 is good.

Hello Paul,
Many thanks for your response to my plea for help.
t may well be that I made a mistake to employ aluminum arms but we shall see as this is a frame wound wire antenna and not to be confused with a loop antenna made from say copper pipe. I am grasping at straws here!
I will most certainly Google Kencove.com to see the fiberglass rods.
If you know of a motor gear reduction to control the 25 pf variable capacitor I would be obliged to learn of a supplier.
Cheers
Steve Roberts VE3LEH

Hi Paul/Dale,
The short answer is no I had not thought of stepper motor. You are talking of those steppe motors used on CNC machines???
Do you have a supplier in mind?
My new mast was delivered today and it was aluminum instead of steel but suppler said keep it for same price as their mistake. It is 1/4" thick wall so will do a good job and never need painting.
Attached is digi pic of completed spider hub and I sure hope it is usable if not I will have to re make it in solid nylon.
Well thank you for your continued help it is indeed appreciated.
Cheers

8515. Frame antenna versus multiturn small loop antenna - comments

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-04-29 00:43:46 UTC
From: vaclav_sal
Topic: 8502 Message: 8515

I am not sure I agree with using term "frame antenna".
Perhaps basic definition of small loop antenna is in order.
We should all agree that we are talking about a resonant circuit of dimensions (diameter) near 1/10 of wavelength.
As any resonant circuit, the properties are influenced by nearby objects. Hence making the support structure out of metal will have an effect. (I am not saying it is wrong!) Common wisdom also states that immediate or more technically - near electromagnetic field - is "strong" - same as any antenna, but since we have a small dimensions is must be stronger in comparison with say half wavelength dipole.

I do not believe that calling the antenna "frame antenna" is sound technical reason not to consider effect of the metallic support.

I believe that more descriptive term would be "multiturn loop antenna" anyway.

I did not notice, maybe I missed it, any author's comments on how much power can be safely applied to his design without "arcing".

Actually I wonder if radial distance of individual turns, and insulation from supporting booms is rather critical and at what power level.

From: neilbanera
Topic: 8519 Message: 8519

I am plagued with RFI in my urban location. I replaced my random length antenna with a PAR end-fed SWL antenna, which reduced the noise level from S9+20 to S9 on 10 MHz...thank you PAR, but still too noisy. I am considering a loop antenna due to its nulling capability but I think I understand that the nulling capability decreases with increasing frequency. So a loop antenna may not be of much help at frequencies of 10 MHz or more. Is that correct? And is anyone aware of published material or a graph which shows nulling of a loop antenna versus received frequency?

Thanks to all,

Neil

With any balanced antenna,(loops, doublets, dipoles, folded dipoles, etc.) positive going noise on one side is cancelled by negative going noise at any instant on the other side. But this applies to local QRN and sadly not to a neighbourhood full of square wave producing far-eastern toys. A single wire or whip is going to be noisier on receive as there is no cancellation effect. Good luck, Mike G4HOL

The nulls are very sharp- so if you have more than one noise source and they are either not on the same azimuth angle or 180 degrees opposed- you are not likely to reduce your local noise much.
On the EF-SWL, make sure you have a good RF ground at the matchbox to prevent common mode noise coming from your home out to the antenna and being brought back into the home via differential mode.

I'm using the MFJ-1026 to eliminate plasma tv noise from my neighbor. It does an amazing job. You must provide a dedicated receiving antenna that picks up the noise as well as or better than your main antenna. Using a band scope (panadapter) makes adjustment easy.

From: ve3pcd
Topic: 8523 Message: 8523

Hello Folks,

I am in the process of building a mag loop out of .5'' copper tubing; I have not decided as yet how to feed it I am lookng at the best options. My question is this; Can I use a smaller dia. copper tube of the correct (loop / 5) length bent into a circle (like the faraday loop and feed it this way?

I would rather not have to use the faraday loop, looks too complicated to build, so it's either a gamma match or smaller loop made of copper.

From: Andrew
Topic: 8516 Message: 8524

My first transmitting loop of 3' dia had a bandwidth of 500khz@28Mhz to 3.5khz@7Mhz.
Care to be specific?

There is no cut length for a magnetic loop because it is tuned via its tuning capacitor.
Think of it as an LC tank circuit who's bandwidth is widened with reduced efficiency.

Topic: 8517 Message: 8525

Hi Drew, it depends on your paint and how well your loop is already protected from the elements. The worst bit to worry about is the high voltage tuning end which is very conscious of any reduction in resistances.

I was thinking along the lines of a full wave loop made for a "specific" band using the classic 1005/F(mhz)

Say for instance I made a loop for the 40m band using 1005/f(mhz) cut at the middle of the band. what kind of spread (Khz) would i have from center for the swr to be 2:1 or less without a tuner?

There's a much simpler and less expensive way of feeding a transmitting loop:

http://www.home.earthlink.net/~christrask/Paper012.html

No Faraday loop, no vacuum capacitor, no gamma match.

From: Steve Roberts
Topic: 8502 Message: 8528

Hello Vaclav,
I would firstly thank you for your observations and comments regarding the 80 meter wire wound (frame) antenna.
The author Harry Lythall - SM0VPO did in fact use plastic coated metal arms and found them to be suitable. However what you say about my central aluminum hub spider could well be very valid. I have given consideration to your comments and have reached the conclusion I am to far ahead as the spider hub is now finished, see attachment. However because of your valid comments I am considering a modification whereby the arms instead of coming out of the hub at 0 degrees to have them angled at say 15 degrees. The effect of this would be to displace the spider hub outside of the windings much like the cloths dryer in the garden but of coarse in my case in the vertical plane. This I believe I can do by machining some 15 degree wedges.
The 25 pf variable capacitor is being made as of right now by Vasile in Western Canada.
I see no author mention of power to be applied and I was planning on 100 watts.
I have changed the author suggested McDonald drinking straws through the metal arms to rubber grommets and hope these will do a good job of insulating the insulated multi strand wire from the metal arms.
Once again I do thank you for your interest, I am a mechanical engineer overhead crane designer struggling to understand the magic of antennas.

Subject: [loopantennas] Frame antenna versus multiturn small loop antenna - comments

I am not sure I agree with using term "frame antenna".
Perhaps basic definition of small loop antenna is in order.
We should all agree that we are talking about a resonant circuit of dimensions (diameter) near 1/10 of wavelength.
As any resonant circuit, the properties are influenced by nearby objects. Hence making the support structure out of metal will have an effect. (I am not saying it is wrong!) Common wisdom also states that immediate or more technically - near electromagnetic field - is "strong" - same as any antenna, but since we have a small dimensions is must be stronger in comparison with say half wavelength dipole.

I do not believe that calling the antenna "frame antenna" is sound technical reason not to consider effect of the metallic support.

I believe that more descriptive term would be "multiturn loop antenna" anyway.

I did not notice, maybe I missed it, any author's comments on how much power can be safely applied to his design without "arcing".

Actually I wonder if radial distance of individual turns, and insulation from supporting booms is rather critical and at what power level.

> I am plagued with RFI in my urban location. I replaced my random length antenna with a PAR end-fed SWL antenna, which reduced the noise level from S9+20 to S9 on 10 MHz...thank you PAR, but still too noisy. I am considering a loop antenna due to its nulling capability but I think I understand that the nulling capability decreases with increasing frequency. So a loop antenna may not be of much help at frequencies of 10 MHz or more. Is that correct? And is anyone aware of published material or a graph which shows nulling of a loop antenna versus received frequency?
>
> Thanks to all,
>
> Neil
>
Hi Neil,

The small loop antenna has figure 8 pattern (sharp null) only for vertically polarized waves and that is for all frequencies for which the loop length is less than 0.1 of wavelength. For other wave polarizations the null is no sharp or there will be no null at all. Most of the waves comming from the ionosphere have random polarization which is not stable and changes sometimes very quickly. That is the reason why the loop has unstable directivity on higher bands. The small loop will be effective for local man made noise since its polarization usually (but not always) is vertical irrespective of the frequency. You should expect very good loop directivity for local noise. Also for nearby LW and MW stations during daytime and not so good for the night time. On SW sometimes you will have directivity but it will be very unstable.

My suggestion is a Timewave ANC-4 or similar noise phasing device. I live in a basement apartment condo suite, and RFI is unreal here! However, I now have a Miniwhip by PA0RDT:

http://www.radiopassioni.it/pdf/pa0rdt-Mini-Whip.PDF

This is a very low profile, excellent active antenna working from 10 kHz to 30 MHz, and I have mine about 4m up off a tree limb, 5-6m from the building. I can routinely receive WWVB (60kHz) at S7 to S9. Never had that before! ;-)

I use the ANC-4 indoors, and any localized RFI also gets hit by the ANC unit. I use the built in whip, and have nulled S9+10 noise to well below S4 with it. S7-S9 noise CAN often be almost eliminated with careful phasing. I assist this effort using the DSP filtering on my R75 - noiseblanker, noise reduction, etc. The ANC-4 does a great job getting most of the mian noise out of the signal path to the rig. Worth a look.

Thanks to all for the feedback.

Currently my PAR antenna is mounted as a sloper running parallel (N - S) to the back fence approximately 40 feet from the surrounding houses...this is the farthest away from all houses I can get, and is also parallel to the pole-mounted electrical supply lines along the streets. The upper end of the 45 foot antenna is about 30 feet high in an eucalyptus tree, with the last (upper)8 feet being vertical downward. The ground rod at the matchbox is 5/8 inch copper-clad steel driven 9 and 1/2 feet into the moist ground (6 inches exposed). The matchbox is grounded to the ground rod by a 6 inch wire...I have tried different ground configurations for the matchbox. As an experiment I have been running the radio, a FRG 7, on internal batteries by the matchbox. The radio is connected to the matchbox with 18 inches of RG8 mini foam cable. I am doing this to avoid RFI pickup along the ultimate feedline which would have to be about 80 feet long and also rise to the second floor of my house. I also have a 3 foot 1/2 inch copper pipe driven into the ground as a ground located about 16 feet from the matchbox to which I have tested grounding the radio, but with no reduction in noise. That ground wire is parallel to the antenna and lies on the surface of the ground.

My latest question is whether changing the sloper antenna to a vertical rectangle or delta (triangle) loop antenna would null noise from the street power lines which would be broadside to the antenna (and noise from the nearest houses which are also broadside to the antenna). I assume that I would attach one end of the antenna to the antenna terminal of the matchbox (which is a 9:1 balun) and the other end of the antenna to the ground terminal of the antenna side of the balun, effectively creating a loop. Is my thinking correct?

Finally, I will borrow my friend's portable SW radio and walk the surrounding streets to determine if the RFI is general or if there are any hotspots. Personally, I find the RFI issue intriguing and disappointing. This issue did not exist 20 years ago when I last used my FRG 7 (I am retired now) and shows the kind of electromagnetic "soup" we are now immersed in.

Thanks again to all...I really appreciate your feedback,

Neil

8533. 80M Horizontal Loop in attic?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-03 13:51:50 UTC
From: kj4wrk
Topic: 8533 Message: 8533

Hi Everyone,
I live in an antenna-restricted community and want an HF antenna with as much coverage as possible. I'd like to work 40m-6m, but 80m would be nice as well. 160m's probably out of the question.

My setup is: Yaesu 897D with an LDG 100 Pro II tuner, a Balun Designs 4:1 Balun feeding 450 ohm window line to the loop in the attic. I plan on constructing the loop from 14 gauge stranded wire with insulation and ceramic insulators.

I believe I can put a 40m horizontal loop in the attic with no problems. but I've wondered what would be the effect of putting in the extra wire and artfully adding some bends in the wire (zig-zag or similar) to get to 80m.

I imagine it would affect propagation and possible even not tune correctly on the amateur bands. My neighbor has an antenna analyzer, so I can get the basic tuning and done that way, but I'd prefer not to spend hours in a hot attic reinstalling the antenna if I can avoid it.

Thanks and 73,

Steve (KJ4WRK)

Steve,
A few years ago there appeared in QST an article on a ' Baby Loop ',
it covered 80m but was only the footprint of a 40m version.
It was basically done by a small coil on a PVC former at the 1/4 wave points
as I recall.
I am not a member of ARRL so sorry cant look it up for you.
Having spent many hours on antennas in our loft I know the feeling, you either need
a few layers on or are melting hi!

Steve;
You might consider cutting the loop opposite the feed point. This would turn it into a squashed 80 meter dipole and would probably be a lot more efficient on 80 than the loop was. If this works out, you might be able to rig up a relay or switch to open and close the loop.

That's not a bad suggestion. I may try that. One site I saw on the internet suggested that I could get creative and add some bends to the loop, so I'll give that a try.

It looks like I have a week of cool weather ahead, so I expect I'll be up in the attic pulling wire. Hopefully, my balun and ladder line show up in the mail soon.

Actually, it was here where I first saw a mention of it:
http://mysite.verizon.net/ka1fsb/loopants.html#goodturn

I've read several of the Cebik articles now and I'm encouraged that I should be able to make something that works well enough to get out on the bands of interest. Multiband operation is very important to me, so my first priority will be that.

I've decided to cheat a bit and use PVC pipes to poke the corners of the antenna out into the far edges of the attic. The idea of crawling through insulation covered joists above a 2 story family room isn't especially appealing.

I HAVE FOR HAM RADIO PROJECTS HV CAPACITOR AND BUTTERFLY CAPACITOR KITS FOR SALE

I used a CNC machine to cut the blades and a lot of elbow grease to clean after by hand.

My spacers are 0.25"and 0.500".

The size are 5.5"x4"x3.25"

I can do custommade capacitors.

I need only how many pF and voltage(distance beetween blades)

Here the relatin between air gap and voltage

air
gap voltage

.030 950 V
.032 1100 V
.037* 1325 V
.045 1550 V
.075 2500 V
.080 2700 V
.100 3100 V
.120 3500 V
.140 3700 V

Hi Drew,
Attached is a picture of a 25 pf capacitor that has just been manufactured for me by "Vasile" in Galgary Alberta. If you want his contac details let me know.

Regards,

Hi all.
I am new at this group and I would like to build a magnetic loop for general SWL. Is there any simple "worked" plans that can guarantee a success?
I have already tried with a capacitor taken from an old transistor but without success. My radio is a handheld scanner Yupiteru MVT-7100 and it seems that is not particularly fond of short-circuited the two parts of his antenna. At least that is what read.
Thank you in advance for any help.
John.

Here are a few tunable loops:

http://www.home.earthlink.net/~christrask/Paper011.html

http://www.home.earthlink.net/~christrask/Paper012.html

http://www.home.earthlink.net/~christrask/Paper018.html

In the group files section you'll find similar papers for a wideband loop antenna amplifier and a generalized tutorial on loop antennas.

8546. Advice on feeding my Mag loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-13 17:33:26 UTC
From: ve3pcd
Topic: 8546 Message: 8546

Folks,

I am building a loop of 1/2" copper tubing ,I am also using a Vacuum Cap and motor to tune it. My confusion is feeding it, I have decided to go with the faraday small loop to feed the big loop but not sure if it's working because I cant seem to get a good SWR match. Here is how I have built the faraday loop.
1. small copper tubing circled into a small loop 1/5 the size of the main loop.
2. One end of the small loop is connected to center of the female coax connector.
3. The other end of the small loop it connected to the ground side of the coax connector.

is this correct, and if so how to I tune for best SWR?

I have been considering buying a K9AY antenna but can only have it up during the late fall through spring. There is no way I can keep it up all year because it would have to be in my backyard and I would need to cut the grass where it is installed. Down it would have to come every spring.

So I recently saw an ad for the RF PRO-1A in QST and thought that it might be a decent RX antenna for my situation that I could keep it up year round. Would mount it on the side of my house and turn it with a cheap rotor.
http://www.pixelsatradio.com/PDF/RF_PRO-1A_Cut_sheet.pdf

It would be used in conjunction with my Flex-5000, a SteppIR BigIR for 80-10 and an inverted L for 160. Since my Flex-5000 has diversity RX my thought was that using the RF PRO-1A and one of my TX antennas would be a good combination.

So my questions are there any RF PRO-1A users on the list and if so what do they think of the RF PRO-1A in general and especially on 160/80?

Your goal for an 80/160 RX antenna should be to maximize the RX Directivity Factor (RDF- see W8JI site or ON4UN book).
A loop comes in around 4. See:
http://www.k7tjr.com/rx1comparison.htm

The K9AY is remarkably better. I use Beverages on 40-->160 and have not found anything that can compare. However, my half sized Flag does outperform my 7' shielded/broadband loop consistantly- just as their respective RDF's predicts it should.

Dale W4OP

Zack, providing you don't suffer from high local noise the K9AY is a much better antenna. One way round the grass cutting issue is to raise the base of the antenna say about 5-6 ft above the ground i.e. the base is horizontal. I use two K9AYs with this configuration as a 200kHz to 2MHz phase array. My experience with the K9AY would indicate that having the antenna elevated does improve the directivity.

8550. RE: [loopantennas] Advice on feeding my Mag loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-13 23:24:22 UTC
From: Ray Phillips
Topic: 8546 Message: 8550

Method one:-

Start with a loop obviously bigger than 20%. This is called aiming off - by deliberately missing a target in a known direction, you don't have to guess the direction of the target. In this case, the pickup loop must have to be smaller.
Tune the loop to resonance on a frequency in the centre of the TX range (listen for a peak in the noise).
Test the SWR.
If the SWR is out of tolerance then make the loop a bit smaller.
Retest and repeat until success.

Method two:-

If you have an antenna tester:-

Tune the main loop to resonance on a frequency in the centre of the TX range. Remember, resonance occurs when the reactance is zero.

If the pickup loop impedance at resonance is lower than 50 Ohms, make a bigger pickup loop; repeat until pickup loop impedance is 50 Ohms or just a bit larger. Fine tune the impedance by rotating the pickup loop in either the vertical plane axis or the azimuth plane axis (tilt it or twist it) until the impedance is 50 Ohms.

As you make the fine adjustment, you may need to retune the resonance due to interaction between the main and pickup loops.

Check at either end of the TX range; re-adjust and compromise as necessary.

If you don't have an antenna tester:-

Tune the main loop to a frequency in the centre of the TX range by listening for a peak in the noise.

Twist or tilt the pickup loop a few degrees at a time to get the best SWR however you are measuring it.

If the SWR is sitll not acceptable guess whether the loop is too large or too samall and make a new one. Twist or tilt to fine tune. If the SWR gets worse, you guessed wrong; make another pickup loop and try again.

Check both ends of the TX range.

If the impedance at resonance gets near 12.5 or 200 Ohms, stick in a 1:4
or 4:1 (respectively) guanella balun and the job's done.

I have had my PRO-1a for several months. I mounted it on a 5' mast section mounted to the skirt of my deck, which is just under 2' off the ground. I had, over three plus decades, had long wires, TTFD's, large loops, A-D Slopers, etc, and fed them with everything - single wire, 450 Ohm balanced line, coax, you name it. They all picked up the sporadic high tension line noise, from defective compression insulators, and, most lately, the reradiated by my own house wiring trash from switching supply wall warts, PC's, HDTV's, satelite rcvr's, etc. I wanted to resurrect my SWLing - but the noise was horrific - and, my favorite old pine tree/support had to come down.

I thought about it for months - then took the plunge. It was a bundle of bucks, but worth it. I fed it with RG-6 Quad. I lined the loop parallel to my house - and 11 feet away from the back wall. It nulled the hideous power line noise - and reradiated hash from the house - at that position, so I didn't buy a rotator. Additionally, it's sky-wave directionality wasn't as pronounced, further negating the need to turn it - here. It is quite directional on the local NDB 224 kHz (BH) and MW stations, alike. It has worked quite well for three plus months now - weathered some heavy rain & wind quite well, too. Again, a lot of money - but a complete 'package' - and seemingly worth it.

It does have a 'key' input on the desk mounted power inserter/power switch - you can connect it to your transceiver mic/key line to de-sens the antenna during transmissions on adjacent antennas.

John

Peter,
mine antenna is a copy of Ken's design
http://www.qrpbuilder.com/downloads/loop%20antenna%20110310.pdf
Check his design. He has great detailed drawings of his antenna.

Here is my faraday pickup loop.

Made of two halfs of 3/8 soft copper.
I inserted RG8 coax minus outside insulation and braid into one half BEFORE bending it in half circle.
The center of feed coax is connected to the center of faraday half loop coax - bottom end.
The other end of the center of this faraday coax insert is connected to the other copper half loop - top end.
At the feed end (bottom half) both copper loop halfs are connected via PL plug body.

I am about to fine tune my loop - it looks as my lower frequency is bellow 10 MHZ and top somewhere near 16 MHz.

I still have some mechanical issues to work out before checking the SWR.

I have had mine up for almost a year now ,i used it all last winter by itself ,this spring i installed the vertical.......I use it mainly for MW DXing and as a quiet alt. to a vertical for SW listening, and can report that it has opened the world to me.

I have mine setup on a 10 foot tower and rotator about 12 feet away from the power line that goes into the house and about 25 feet away from the house,fed with RG-6 buried in conduit to the radio , i expected to get all kinds of static there but it seems fine.

You have a really nice radio-antennas ,so i wouldn't expect you to be WOW'ed by the pixel loop performance ,but if i understand your question ? you are thinking of using it as a second antenna in a phased array?

For about 2 months i've had the Pixel loop , MFJ vertical and a quantum phaser running here, performance wise the loop is quieter than the vertical ,(no surprise there) but as a phasing array it does bring in the DX ,and i can even get rid of noises if they are on the right heading.

I have never had room for a K9ay... or 4 :) ,wish i did ,i suspect it would be better at getting very weak signals because of the bigger appeture ?
, however most of the time it's the conditions that decide if Dx will come your way or not, by that i mean if there is no signal there? ,there isn't any way to drag it out of the soup,unless your in a very quiet environment and can turn the gain all the way up,(add more amp).

The directtivity of this loop is good ,were i get into problems is having a station 180 degrees from the station i'm trying too ID,that's why i went with a phasing setup.

Being in N/E Nebraska i'm more or less in the central part of the continent,and several times already i have received stations from my north and south on the same freq , a thing not possible before this .

Hope i understood you correctly, if not just ask again :P

Sorry I didn't get back to you sooner, I have a lot of contracted preventative maintenance work and I like to get as much of it out of the way plus we had a couple of days of record temps in the low 90's

The problem with mixing silver rod and normal solder is you have to hear the rod to a much higher temperature so if the other joint is too close it's literally spit the solder right out of the joint. You can use a heat trap paste but that's not very cost effective for a one time deal. Of course you can use the old standby of wrapping a wet rag around the regular solder joint if there is room. Be aware that the rag can dry out amazingly fast and catch fire. I usually fill and old dish soap battle with water and you can squirt it to keep the rag wet. I have to do that when I'm working around shut off valves, pressure switches and expansion valves so you don't ruin the seats and seals.

Hello Folks,

I have just received a recent review comparing the above product to
the Wellbrook ALA1530, it can be found at:

http://www.wellbrook.uk.com/reviews/ALA1530-vs-RFPRO-1AReview.pdf

The review has a link to some MP3 recordings of the s/n comparisons from
the LW band up to the 13m broadcast Band

My experience with the Wellbrook was unfortunate due to the fact that there is no North American distributor for this product. I spent over $80.00 sending various parts of a Wellbrook antenna back and forth to Great Britain due to the fact that I had zero signal with the sample(s) that I had connected to a TenTec RX-350 shortwave receiver.

Either the electronics were somehow damaged in transit (this was right after 9/11, so maybe they x-rayed the suspicious looking loop???), the antenna was defective from manufacture, or the antenna was desensitized from close proximity to some powerful broadcast FM antennas located within a block of my residence. Unfortunately, since everything on the Wellbrook that I received was potted in putty, there was no way that I could self-repair any suspected defective parts and was stuck sending the various insundry parts of the antenna back to Great Britain for a replacement and refund. While the problems with the Wellbrook could certainly have stemmed from the proximity to the broadcast FM antennas (at 10 Mile and Greenfield in a northern suburb of Detroit for those familiar with the area), I am forever soured on ordering from overseas due to the logistics of overseas shipping. I must say that Andy treated me quite fairly and did refund my money, but the postage expenses made this a losing proposition for both sides. A North American dealership or distributor would have made all of these logistical difficulties less traumatic.

For North American users, my story might be a factor in determining which loop to buy.

Guy Atkins received nothing with the PRO-1A on the 25mb? Wow. Gotta wonder about that. Mine has worked quite well, thus far. Of course, I only had the comparison of the Wellbrook and Pixel loops provided by Pixel and eham reviews to go by - and the Pixel generally did better. Most folks still don't use SDR's, either - in my case, I have used it mainly on my Palstar R30A - and Lowe HF-150. I even hooked up my old much-modified JRC NRD525 - and it was impressive there, too. It's greatest attribute, to me, is it's ability to null both the high tension line noise and the house reradiated digital hash from switching wall warts, PC's, HD-TV's, and even satelite rcvr's. It came complete - except for the RG-6 quad and f-connectors - even with an F-female to PL259 adapter.

As an aside, BNC connectors were never meant for outside 'in the weather' use - they are faster on/off interconnect cable connectors, mainly used with test equipment. Of course, even at 30 MHz, 100 ft of RG-58 has measured loss - RG-6 Quad is much lower in loss. RG-58C/U is even lossier - but more flexible - RG-8X would be better for a long outdoor run, if you cannot use RG-6 quad.

John

From: Jack Smith
Topic: 8556 Message: 8559

One comment on RG-6 versus RG-58...

Most RG-6 has a thin copper layer on top of a steel center conductor. Above a few MHz, the loss is about the same as for a solid copper conductor and less than RG-58. However, below a few MHz, the loss increases as the copper isn't thick enough. This can amount to a dB or two more loss for RG-6 compared with RG-58 for a typical run at 100 KHz.

In the overall scheme of things, a dB or two won't be noticed in this frequency range, but it's a real effect. If you want the best performance with RG-6, look for a cable with solid copper center conductor. It will also be a bit easier to handle as it isn't quite as stiff.

A BNC can be used outside, but requires weatherproofing with self-fusing tape, coax-seal or the like. BNCs in this regard are no different than UHF connectors.

Hi John,

You are not reading the charts correctly. The 25mb portion indicates that the RF PRO-1A was never the best antenna on the frequencies checked for that band. See the legend (caption) below each of the column charts.

It was the same findings on the 41, 31, and 13mb also... The RF PRO-1A never provided a better S/N than the ALA1530 on those bands. Please re-read the review to understand the metrics I used to evaluate the loops.

In the XLS file of captured S/N data (within the ZIP file you can download), you can see the S/N values of all of the signals measured on all bands, for both of the antennas. They show that the RF PRO-1A received the same stations as the Wellbrook loop for the 25, 41, 31, and 25 meter bands; however, the RF PRO-1A never equalled or surpassed the ALA1530 on these bands.

73,

Guy Atkins
Puyallup, WA

Hello Guy,

It's been a while since my last R'burg trip. Well, you were right - my cursory view of your charts was too brief. But - to look at your 25mb data - the Pixel antenna never had a better s/n ratio than the W-B on 17 compared signals. Further, the sum of all s/n for the antennas appears to be 290 for the W-B and 210 for the Pixel. You state that is a ratio - which would give the W-B a 290/210 s/n ratio improvement over the Pixel - that's a net +2.8 db cumulative s/n improvement for 17 signals - in general listening, how is that ever heard? I wonder how your selective use of your SDR's 'AVE' function - to help settle it's readings - may have influenced your results.

I see Wellbrook uses your article on their site. Price-wise, the 1530, available in models from $320-$400, and poly or Al tubes, plus s/h from the UK, can easily cost more than the Pixel. Additionally, repair/replacement parts - like the encapsulted preamp - will be pricey. I got a 'deal' from Pixel - they threw in s/h! I immediately had buyer's remorse - I had designed, built, and used balanced loops - remotely tuned and broadband - for many years - and I am 'frugal'. I had just spent $400 - on an 'appliance' antenna! Then it arrived - and I quickly had it up and going - and could 'hear' something other than powerline arcs and house-generated RFI. I'm still happy with it.

Take care.

John

Hi John,

I didn't realize it was John *Tow* I was replying to! Whoa... it's been a long time since we last visited at that DXers' GTG. My previous trip there was three years ago.

Regarding the ratio you mentioned between the columns or charts, there is no ratio or relationship between them. The left hand pairs of columns for each meter band are simply the total of the number of times an antenna gave the best signal (ie, best signal to noise ratio as measured by Perseus). In the case of the 25mb comparisons that you first pointed out, every signal was better on the ALA1530.

The right hand column also has no ratio going on; it is just the sum total of all S/N readings for each loop, per band. So, the only ratios used in my review are the signal-to-noise ratios of the individual signal receptions with each antenna.

If you haven't yet downloaded and looked at the XLS file of data I provided in the link at the end of the review, that will help show the actual S/N results in detail.

Personally, I think it's a good thing when specialty manufacturers pot or encapsulate their devices when they contain unique designs that represent tons of design effort. Kiwa Electronics does this also, and I think it's a good way to frustrate or prevent reverse engineering. The designers deserve to take this approach to help maintain their businesses' profitability. Practically speaking, it can also help avoid shock or thermal damage to the components.

73,

Guy

8564. Pyramid Star Horizontal Loop?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-17 17:02:54 UTC
From: kj4wrk
Topic: 8564 Message: 8564

Hi All,

I'm planning an attic install of a horizontal loop to cover 40m and up for multiband operations. A 40m loop requires 140.5' of wire, but my available space for an antenna is a 30' square which would yield 120' if I were to only string wire around the perimeter.

Cebik's site has an article on a 40m star shaped loop which answered an earlier question about my being creative with the shape of a horizontal loop (http://www.cebik.com/content/a10/wire/40star.html)

In spite of my space limitations, I can easily manage the 140.5' length requirement if I pull the wire up into a loose pyramid shape. In fact, I could pull in as much as 173 feet that way. The apex of each star section would be 18" away from the apex of the other star sections. In order to construct the pyramid star loop, I'd follow about a foot under the roof
at a 30 degree angle.

Cebik's site seems to imply that I can use extra length (http://www.cebik.com/content/fdim/atl1.html), but I'd like some other opinions.

This is my signal chain:

Yaesu 897 -- 6' RG-8X --> LDG 100Pro Tuner -- 20' RG-8X -->
Balun Designs 4:1 --> 40' 450 ohm window line --> 40m loop

The question is: would the extra length (173' vs 140.5') cause issues or should I just stick with the nominal length?

Thanks and 73,
Steve (KJ4WRK)

8565. Feedline wire type

From: Garry
Topic: 8565 Message: 8565

Hello, I am re-constructing balanced feedline to feed a 160 meter loop multiband antenna. For a portion of this, I am using 14 ga wire for a run of approx 80 feet. The wire will be under tension for spacing and will not have individual spacers in the line. Is it better to use solid or stranded wire for this application?

Thanks - Garry - K4OR

No, I think he ment: he received no Channel better with the Pixel Loops - or the other way raound: the Ala was better with every station he received.

The mp3's are quite impressing, I wonder what makes the two loops working so different at some frequencies?!

73, Stephan

From: kj4wrk
Topic: 8564 Message: 8567

Upon further reading (which is usually helpful), Cebik said that a 1.25 WL star lowered the TOA and I believe I have very good chance of success.

My antenna's slightly different since I'm elevating the inner section of the star, but I don't foresee any issues with that.

Now I just need to avoid falling through the ceiling. :)

First of all....Scrap the 4:1 balun. The impedance of that loop is already low (less than 100 ohms on 40m) and you will be stepping it down 4 times lower. A 1:1 balun would make more sense but there's not going to be anything 'balanced' about this antenna since it will be exposed to all kinds of objects. I would just try making the loop as large as possible. The zig zag idea isn't going to help anything. Use the tuner to make up for non=resonance
I would go like this:
897 > RG8x > Line isolator > LDG tuner.
Try to put the tuner as close to the antenna as possible and run coax all the way to it. The window line would radiate some due to the antenna unbalance and it will pick up even more noise from the house.
The line isolator will help decouple the shield of the coax from common mode currents. You might need another one at the rig. See Radio Works for an example of this product.
Keep in mind that the strongest RF field will be directly under the loop. That's not a good thing! It's like the primary of a transformer and your house wiring is the secondary. Expect RFI problems of all kinds. A shortened, loaded dipole up along the ridge might be a better idea.

<Excess quoting trimmed by moderator - hint, hint>

Gary,
I use solid #14.

I also use ladderlock spacers..not a good idea to let the wind set your
spacing.

good luck, Jim WY4R

Wait: are you saying you will maintain spacing over the 80 foot length by tension only? If so you definitely want to use copper clad steel wire because you are going to have to really crank up the tension and soft-drawn copper will stretch.

I tried that idea using 12ga copper clad steel and turnbuckles for tension over a 50 ft span (4"spacing). Didn't work! I ended up with several spacers. Maybe if you spaced them 12" it would work but why bother?

From: kj4wrk
Topic: 8564 Message: 8572

Hi Steve,
Thanks for your reply. The reason I had the balanced line and the 4:1 balun was to enable multiband operation. I expect I'll see a pretty broad range of impedances at other frequencies and the balun will pull them down to something that's hopefully manageable by the tuner.

Given the dimensions of my available space in the attic, I can only manage 120 feet of wire unless I get creative and add a few bends. Pulling the sides upwards to follow the roofline will allow me to add as many as 55 extra feet to the antenna. My plan is to pull up the sides enough to get 1 WL closed loop at 40m.

Cebiks article was encouraging to that end. The 40m star he modeled had pretty good performance in spite of being pulled inwards til the centers were close to touching.

I do have a few metal objects in that area, but they're not significant and hopefully, won't be an issue.

Regards,
Steve (KJ4WRK)

8573. Re: Feedline wire type

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-20 16:21:54 UTC
From: Garry
Topic: 8565 Message: 8573

Thanks for the response. I may have to rethink this. My thinking was
under tension I could maintain the spacing where I was going to start
out with 4" and move to 6" if necessary. I was going to replace a length of ladder line I have running across the back of my house to make the transmission line appear invisible for that particular run of line anchored just below the shack window which is on a second floor on one end, and the end of the house on the other. Guess I'll have to make a few spacers.

Thanks,
Garry

8574. Receiving Loop - Faraday?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-22 12:01:40 UTC
From: Ralph
Topic: 8574 Message: 8574

A friend of mine has been experimenting with small loops for receiving tropical band signals (60 meters and 90 meters).

He has had a lot of success with a small loop, single turn, about 30' in diameter, fed thru a Wellbrook amplifying unit.

I am attempting to duplicate his success and improve upon it, but don't want to spend the big bucks for the Wellbrook.

So . . .

I have constructed the loop form out of 1" PVC, about 30' in diameter. Have coax run thru it, one turn. Am building a broadband RF amp to put next to unit, which will be remote from my receiver, up in attic, and situated/rotated for lowest electrical noise and therefore, theoretically, highest clean signal-to-noise.

My questions:

1. Should I make this a shielded loop? Can open the coax at far end of loop and shield the connection at near end of loop. But will not add tuning capacitor, as loop will be remote from listening post.

2. Should I use a 'Faraday loop' connection for the main loop? I keep reading how quiet the Faraday loop structure is, but it only seems to be used for coupling loops. In this case, there is no coupling loop, just a single large small loop. Would the Faraday method improve results? (Shield connected to center at the 'break', and shields connected at near end.)

Thoughts welcomed!

Hi Ralph,

I don't get the full gist of what you are proposing but;

If you take the signal straight off the tuned loop, you need a high input impedance amplifier or you will load the tuned coil too much. The lower the impedance presented to the tuned loop, the lower the coil Q, the lower the output voltage, the worse the tuning bandwidth is and you might just as well not use a tuned loop at all. I would use a loop pickup rather than try to pick the voltage off the
tuned loop. A one-fifth pickup loop will present a low input impedance
to the amplifier and allows the use of traditional low-input-impedance
amplifiers. Look at
http://www.brisdance.com/vk4amz/files/Download/UnderMagLoop.pdf for some
good guts on magnetic loops from a man who can communicate to us mere
mortals who don't have the mathematical skills other paper writers
expect.

The tuning capacitor would best be placed as close as possible to the loop. This means that the capacitor will need to be remotely tuned. As it is a receiving loop and the tuning capacitor won't be subjected to high voltages, varactor tuning will suffice and is a lot simpler than trying to interface a mechanical capacitor to some sort of drive mechanism. It is also a lot cheaper than buying a vacuum capacitor. Oatley electronics in Oz sells a remotely tuned AM varactor kit with inbuilt preamp. It picks its voltage off the tuned loop but has an amplifier input impedance in the 200KOhms region and so should not load the loop to any appreciable amount. The inbuilt preamp op-amp has unity gain somewhere short of 10MHz and would not be suitable for your chosen frequencies but the schematic offers some ideas regarding remote diode tuning and how to interface to an op-amp. Its pdf is http://secure.oatleyelectronics.com/files/K256notes.pdf.

For the loop, just use the braid of the coax - don't worry about the inner. The braid will act like a wire of the same diameter and gives excellent loop Q.

To shield the loop, try wrapping it in one piece of aluminium cooking foil and earth the foil. Some people say shielding doesn't provide any benefits, others disagree. I say try it and see for yourself. Personally, I take advantage of good Q and the resultant narrow tuned bandwidth to provide noise elimination.

All the best,
Ray

8576. Re: Receiving Loop - Faraday?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-23 23:17:01 UTC
From: Stephan Grossklass
Topic: 8574 Message: 8576

First we may need some clarification here - a 30' dia. loop is not what I'd call "small". 30' of /circumference/ may have a better chance of fitting inside an attic, but that's still a bit on the cumbersome side. Maybe 30" then?

There's no way a 30" diameter single-turn coax loop will peak on 90m with typical capacitance values (diode or mechanical), that I know for sure. According to <http://www.66pacific.com/calculators/small_tx_loop_calc.aspx>, over 2 nF would be needed. That's more suited for a "10 to 30" (MHz) job.

Of course there's always the old trick of bumping up inductance with some series inductors (as Sony's AN-LP1 does on the lower bands), but obviously that means additional loss. It may be tolerable in a receiving application given the generally higher noise levels down there, but is something to keep in mind.

The aforementioned varicap tuning would be a good idea indeed (the additional effort when installing a rotor is small potatoes, and you generally do want a way of rotating such a loop) but it seems to me that AM varicap diodes may be even harder to come by than their mechanical colleagues nowadays. For best linearity, they should always be used back-to-back (which is why they made dual diodes).

Broadband operation is not the ideal way of getting a lot of RF power out of a small loop. Remember? Small size, efficiency, broadband - pick any two.
In this case not tuning out the loop inductance means you're seeing that in series with the very small radiation resistance. (For a good match, the next stage input impedance would have to be (Z_ant)*, which unsurprisingly turns out to be pretty much a series or parallel C. In other words, only a *tuned* small loop can be well-matched.)

For broadband use, an amplifier with very LOW input impedance would be required. |wL| is in the low to mid 2-digit ohms range for the 30" dia. loop on 90m to 60m. Maybe some Norton topology.

Whatever you do, don't actively disturb loop symmetry. Declaring one end of your loop "ground" means you can no longer get rid of common-mode signal pickup properly. This also disturbs directionality on higher frequencies - on my AN-LP1 it basically is 90° off from theory above 10 MHz, even with the ominous "filter unit" in the feedline (which seemingly contains two common-mode chokes). So the above broadband amp would need a

balanced input. On tuned loops, the main loop and coupling loop form a balun, thus you can connect coax without issue. If you wanted to use some FET emitter follower directly at the high impedance point, it would have to be a balanced circuit.

The Faraday loop apparently is our classic coupling/pickup loop. The type of conductor you use for it is almost entirely irrelevant, can be any old wire basically. However, you should get it running *very* close to the low-impedance point of the main loop, opposite the tuning capacitor (/ varicap). Tweaking the length of that segment also allows fine-tuning output impedance (which is not terribly constant, so a good setting has to be found for the whole tuning range) once approximate correct pickup loop circumference has been determined.

Broadband loops are connected directly. Those can be safely stuck into PVC tubing without having to worry about coupling.

Stephan

8577. Faraday - Small Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-05-25 10:55:15 UTC
From: Ralph Perry
Topic: 8577 Message: 8577

Stephan, thanks for the reply.

To clarify, the loop is 30' of coax in circumferenc, inside a PVC.

I am trying to backward engineer what I have already seen being successful, both in a friend's homebrew set-up and also from commercial sources (Wellbrook, AOR).

They both use a broadband amplifier and do not tune the loop, as far as I can see. But I would plan to feed signal outputted from my loop/preamp thru my receiver's usual preselector/preamp and ATU system, so there would be a little bit of juicing-up of the signal, anyway..

So, the only question I am trying to determine is if I would obtain enhanced signal-to-noise by using a Faraday-style connection on this large small loop (gap in coax at top of loop, with one side attached to center conductor; and coax shields at bottom of loop attached, taking feed from center conductor.

Other alternative, suggested to me in this group in an earlier post, is to just take the feed off the shields.

Folks,

I know this is a longshot but here goes...

I have an AEA IsoLoop antenna with the Iso Tuner controller which is used to remotely tune the loop, this controller has a port and can be connected to a computer for tuning the loop also. Question: Does anyone have the software for the controller or have any information at all on connecting this to a computer?, also is anyone out there using this loop?

Hello Folks,

In building my magnetic loop, I have deciseded to feed it with a small faraday loop but not sure if I have it built correctly. I have uploaded some pics of the design and need to confirm that this is correct.

The file folder name is "copper tube Faraday Loop", please have a look at the pics and give some feedback.

Thanks,
Peter

Hello Peter:

I have two of these loops. I also have 3 different models of the controller. None are computer controllers, in fact I am not aware of a PC controller ever being available for the AEA Isoloop. They are manual controllers, that is they have a speed pot, along with two switches for two directions. I would be glad to furnish any other information that you may need concerning this product.

Hello Peter:

I am not at all familiar with the IsoTuner model IT-1 controller. All of my controllers have no keypad, and no DB-9. They have only a 5 pin DIN female, which is the same type of connector used by the old -pre PS2 type PC keyboard connectors. I do have the schematics, and that connector is simply a way to connect the UP/Down, Ground connections to the loop to control the stepper motor mounted inside the loop itself. Sorry if I mislead you. I'll do a search on the IT-1 and see if I can find out more information. It sure would be very nice to have my loops computer controlled.

I have been using my IsoLoop on 20 meters for over a year on/off and have always received excellent reports from DX stations, the only issue I have with it is that it doesnt tune 40 meters that is why I am building a 40 meter loop. Having the IsoTuner - TI-1 does allow better tuning of the loop as well.

I have run many operational tests with the AEA loop. It behaves exactly like a dipole, but at half of the height. Let me explain. I have mine at 16 foot high, for example. That is a quarter wave on 20M. I compared it against a 20M dipole at 33 feet, one half wavelength at 20M. With QRP rigs and/or SDR radios we could never see any difference in the radiation patterns or signal strength. So the big advantage is that the radiation pattern for the vertically mounted loop is that the angle is as low, or maybe a little lower than a dipole at twice the height of the loop.

I understand that vertically mounting the loop has some advantages, but if horizontal works so well for you, probably you don't want to fix something that already works so well. Has anyone ever had a lead on obtaining the IT-1 Iso tuner? I sure would love the have one. I assume that it contains a microprocessor, so copying the schematic would not help without the original source code. Now that I know that the IT-1 Iso tuner exists, I can start searching for a used one on famous auction sites I suppose.

> > I have run many operational tests with the AEA loop. It behaves exactly like a dipole, but at half of the height. Let me explain. I have mine at 16 foot high, for example. That is a quarter wave on 20M. I compared it against a 20M dipole at 33 feet, one half wavelength at 20M. With QRP rigs and/or SDR radios we could never see any difference in the radiation patterns or signal strength. So the big advantage is that the radiation pattern for the vertically mounted loop is that the angle is as low, or maybe a little lower than a dipole at twice the height of the loop.

From: Chevon
Topic: 8585 Message: 8592

I was able to load my Isoloop on 40M by adding a HV doorknob capacitor in parallel to the loop tuner (where the band splits). It loaded up very well and I did make quite a few contacts on CW but the the 2:1 bandwidth was ridiculously narrow, less than 1KHz if I recall.

It was a fun experiment with and then I decided to start building larger loops.

Peter;
here is link to very well made mag loop antenna;
http://www.qrpbuilder.com/downloads/loop%20antenna%20110310.pdf

I made made a faraday loop in the same form and it seemed to work well. I have antenna torn down now to add vacuum variable and new mount. I will submit some photos later when I get a chance.

Hello Peter,

Nice and neat design, afaik, it should work pretty well. I've got
some similar design for receiving, and am pretty happy with this kind
of magnetic loop. (meaning low noise, high efficency into reducing
RFI and so on ...

Best regards

Hmmm, that is a good idea. I wonder if one could replace the capacitor in the IsoLoop to tune 40 meters?

Can you explain a bit more how / where you put this door knob cap?

From: ve3pcd
Topic: 8597 Message: 8597

So I have finally completed my mag loop, but no one seem to hear me.

The loop is very noisy, it picks up just about everything, I hear stations and lots of noise but I have not been able to make not one contact. I had a local ham come one the air for a test and he was not able to hear me, his signal was also weaker that usual. I am not sure what is going on. If anyone with more experience can offer any help it would be apprecated.

Date: 2011-06-02 19:18:36 UTC
From: bconner_01876
Topic: 8598 Message: 8598

I'm thinking of building a version of this antenna for 17 meters.

http://www.infoark.org/InfoArk/Science-Engineering/Radio/Antennas/Gain%20Without%20Pain%20-%20A%20Beam%20Antenna%20for%20Field%20Day-Clarke_2001-06.pdf

I've never used coax phasing lines before, and since they are longer than the distance between the elements, I was wondering about the best way to handle them. Should they be coiled somehow or left loosly looped over the support or what? How do I keep symmetry?

My plan is to forego all the PVC supports shown and just have this as a non-rotatable array suspended by lines on the top and guys at the bottom to hold everything in position.

If anybody has the EZNEC (or MMANA) model for this, I'd love to have a copy to play with!

Usable for fine-tuning high-Q circuitry. At that price you could afford to have a few just lying around.

Topic: 7647 Message: 8604

Hello folks,

I'm new to this group so please let me briefly introduce myself. I'm Daniele Tincani from Livorno, Italy. I'm a SWL (with special interest for LF, MF and low HF) and I like to homebrew simple projects like the one discussed in the attached messages.
I would like to know if someone tried in practice to apply modifications suggested by Chris to the amplfier circuit proposed by John 9V1VV. In particular I would be interested in how to build the input BalBal and the output 1:1:1 BalUn and how connect the latter into the circuit.
Best regards
Daniele

> >
>
> I've seen a number of amplifiers similar to that. The first one that comes to mind is that of the British fellow who has an extensive online presentation of a large loop antenna. Can't recall his name or the URL at the moment, but I'm certain that there are list members who will readily recognize who I'm refering to.
>
> It would be interesting to compare the radiation patterns that result between high input impedance and low input impedance amplifiers used for wideband active loop antenna applications. I suspect that the former approach would deteriorate the null.
>
> One item I find missing from this design is an input BalBal transformer. Such a transformer would serve a number of uses, in particular providing a degree of immunity from common-mode interference such as lightning strikes. It would also provide a ground reference for the antenna proper, and in addition would allow the two transistors to have an identical base voltage. The limiting diodes would be placed across the primary side of

the transformer.
>
> I would also disconnect the two emitters, have a separate biasing resistor from each emitter to ground, and then a suitable capacitor between the two emitters. Then the two capacitors from the collectors to the output transformer primary winding can be eliminated. The 1:1 UnUn output transformer could be replaced with a 1:1:1 BalUn, the centre tap of the primary connected to the supply line. This would increase the P1dB a bit plus raise the gain by an additional 6dB.

From: Daniele
Topic: 8606 Message: 8606

Hello all,

I'm planning to build a wideband active loop antenna for reception, hopefully covering LF to low HF.
Now I'm thinking about how to build the aerial element.
Due to space restrictions, I'm forced to no more than 80 cm diameter. Is this enough for an acceptable antenna efficiency, in principle?
Second questions (very classic!) is: shielded or unshielded?
Third question is: how better is copper tubing - for practical use - in comparison with large-diameter coax cable (or other solutions), in both the shielded and the unshielded cases?
Many thanks in advance for your feedbacks.
Best regards
Daniele

Hi Daniele,

I'm using a 2' (60cm) tuned loop for MW and one about 40cm for SW up to 60M. I haven't built anything under a Meter for LW but I don't see why it couldn't be done.

Tim

How far is this station on 1570KHz from your location? What are your requirements for size and or form factor of this antenna?
Your mileage will vary but there has been a recent thread about small loops such as the Terk Advantage or the Kaito AN-200 (and derivatives). These are small (9") loop antennas which are tunable across the entire AM band. I have also built similar type antennas with a loopstick antenna and tuning capacitor, when one could buy loopstick antennas for AM radios. I have even done this using the coil and capacitor for (Quaker) Oatbox crystal radios. These loops are designed to passively couple to your existing radio and are meant for indoor use.
 A nice feature of the Terk is that there is a 1/8" jack on the back that can be coupled to a wire antenna and ground connection should that be needed. One could also throw wire out the window and wrap the free end around the radio to achieve the same goal. I prefer using the Terk to couple the antenna as it allows a bit more tuning of the antenna coupling to the radio.

I have some low power community broadcasts (emergency, traffic) that I dig out with my Terk. Two are around 1620-1630KHz and another at LAX (about 12 miles distant) at 530KHz that need a bit of help at times - too much computer and other electrical trash in my house!
Good luck,kevinkc6pob

Thanks for the information. I am about 15 miles from this weak station. If I try the wire out the window and wrapped around the receiver and get no results will these antennas you mention be worth trying or should I put something up in the air outside.

Thanks

--- In loopantennas@yahoogroups.com, kevin asato <kc6pob@...> wrote:

>

> How far is this station on 1570KHz from your location? What are your requirements for size and or form factor of this antenna?

> Your mileage will vary but there has been a recent thread about small loops such as the Terk Advantage or the Kaito AN-200 (and derivatives). These are small (9") loop antennas which are tunable across the entire AM band. I have also built similar type antennas with a loopstick antenna and tuning capacitor, when one could buy loopstick antennas for AM radios. I have even done this using the coil and capacitor for (Quaker) Oatbox crystal radios. These loops are designed to passively couple to your existing radio and are meant for indoor use.

> A nice feature of the Terk is that there is a 1/8" jack on the back that can be coupled to a wire antenna and ground connection should that be needed. One could also throw wire out the window and wrap the free end around the radio to achieve the same goal. I prefer using the Terk to couple the antenna as it allows a bit more tuning of the antenna coupling to the radio.

Hello peter

I presume that when you say that a 1.8 degree stepping motor is not tight enough, you mean that it does not have sufficient resolution?

Most hybrid stepping motors have a step size of 1.8 degress. In other types, the step size is typically larger. With the hybrid motor, you have a coiuple of options:
i) use a gear box to improve the resolution
ii) use a microstepping drive, to move the motor a small fraction of a step.

Hi John,

What I meant is that it does not allow me to make very fine adjustments. I have a controller, are you saying that I will need a gearbox as well, and what ratio do you recommend?

Also, would the 1.8 deg stepper be ok with a gearbox?

de Peter,

There are 6:1 reduction drives available on Ebay and elsewhere with 1/4" (6mm) shafts in and out that would give you 540 steps over 180* or 0.3* per step.
Look under Ham radio/parts.

Hi Tim,

Could I also use a DC motor with a variable power controller, or may be a gear motor? All I need is to make very fine adjustments.

The Grundig AN-200 tuned loop runs 25-30$ US on evil-bay, etc. It peaks at ~10 3/16". The rear foot could be cut to lower it to 10". It is quite well made and has a 1/8" jack on the back foot for connection to your receiver - or it can magnetically couple to a portable.

8623. Capacitor connection question, mag loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-06-26 13:36:06 UTC
From: wwblues
Topic: 8623 Message: 8623

Hi, all.
Loop rookie here.
On a magnetic loop, I read about fairly extreme measures to keep any unnecessary resistance out of the loop - silver solder rather than lead or tin, 3/4" pipe or larger rather than 1/2", etc. In considering capacitor types, motorized. Vacuum variables seem to rise to the top, and butterfly capacitors are right behind them. But, when I look at them, I see rather small connection points, wires or screws, which seems to conflict with the effort described above. Is there something I'm missing? Is it a big deal?

From: toddroberts2001@aol.com
Topic: 8623 Message: 8624

Vacuum Variables are sort of a catch 22 when it comes to
transmitting loops. All the information says to never use screw-on
or bolted connections. Vacuum variables are very low loss
but the only way you can make a
connection to a vacuum variable is with a bolt or screw or
some type of clamp. The best way to try to cope is to
use silver-on-silver connections and firmly clamp a silver
strap as tight as possible around the vacuum variable, which
should be silver plated on the outside of the body where
connections are made.

One way around this is to build your own trombone-style
variable capacitor using copper tubes and Teflon sheet for
insulation. This way you can integrate the trombone capacitor
directly into the loop antenna and silver solder all connections.

Also never use wire or "flying leads" when connecting any kind
of capacitor to a transmitting loop. Use only copper strap at least one
inch
wide when making any type of connection to a transmitting loop. Do
not use flexible ground braid when making connections, it is too lossy.

From: vbifyz
Topic: 8626 Message: 8626

Hello Chris and group,

After trying several options (gain, bandwidth, stability - pick any two :)) , I've decided to build the amplifier described in your article WidebandLoopAntennaAmplifierRevA.pdf.
The problem is I don't have the binocular cores made of 61 material, only made of 43 material. I understand this will kill the performance of T3, because it is loaded with the very low input impedance of the second stage.
Question 1: Can 43 material still be used for T6? Its loading impedance is 50 Ohm.
Question 2: If I omit T3 altogether and couple the stages directly (with the necessary bias circuit modifications), how much gain would I lose? My naive opinion is that in the end, voltage gain of the whole amplifier is the ratio of 50 Ohm to the input impedance. I don't see how interstage and output transformers can increase it. T6 is still nice to have for balanced to unbalanced connection and for splitting/combining the power and the signal.

73, Mike

8629. Summary from a newbie on how to build - Is this right?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-06-27 03:32:42 UTC
From: Jim
Topic: 8629 Message: 8629

Hi all,

I would like to build a small, 20m loop. I just read some articles and watched a few YouTube videos and wanted to see if I got this right:

1) Get about 7' of wire.
2) Feed each end into the two terminals of a variable capacitor that will ultimately be at the top of the antenna.
3) Form your circle / square / octagon.
4) For the feedpoint, feed a Faraday loop that will sit at the bottom of the outer loop, butting up against it.
5) Connect to the radio and tune the capacitor for maximum noise.
6) Review SWR's.

A few of questions:

1) Was that close
2) Do you need to match with a Faraday loop (or some other matching network) or can you just feed the outer loop?
3) Since I'm new to this, please explain how we "get away with" not feeding the outer loop and only the Faraday
4) How big is the Faraday loop supposed to be?

In the articles and videos, there were just a few things that seemed to be breezed over.

Thanks a lot! - Jim K9IDX

I had similar concerns until I realized that the VV cap has a specified loss curve which in order to be measured had to be connected by the supplied means, hence the loss included the connection.

Go with the manufacturer supplied connection means.

Jim

Yes, you can probably get away with that. I made T3 and T6 identical so
as to reduce that number of different parts. 43 material performs poorly in
low-impedance circuitry so I use either 61 or 73.

Transformer T3 gives you a current gain factor of 2 (6dB of power gain).
It also provides second-order IMD immunity from even-order products from the
first amplifier stage. So, you'll lose 6dB of gain plus the OIP2 will
suffer.

If that connection is not critical, such that bolts and star washers work, wouldn't 3/4" CATV hard line make a decent loop material then?

8633. Re: [loopantennas] Re: Capacitor connection question, mag loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-07-03 15:28:34 UTC
From: toddroberts2001@aol.com
Topic: 8623 Message: 8633

In a message dated 7/3/2011 11:23:07 A.M. Eastern Daylight Time,
wwblues2@... writes:

Hi Bill,
Bolts and star washers "work", just not as well as silver-soldered
connections when
it comes to transmitting loop connections. Personally I would never use
bolts and
star washers to make connections to a transmitting loop. It can make the
difference between a loop that "works", or one that is an exceptional
performer.
73 - Todd WD4NGG

If that connection is not critical, such that bolts and star washers work,
wouldn't 3/4" CATV hard line make a decent loop material then?

Bill. WW0J

8634. Large-diameter stranded wire or coax?

Topic: 8634 Message: 8634

Hello group,

given a square structure (say 100x100 cm) of PVC tube, 16 mm diameter, and a wide-bandwidth loop preamplifier (http://www.qsl.net/m0ayf/active-loop-receiving-antenna.html), what would you choose for building the loop? Large-diameter stranded wire or coax (RG8, RG213)?

Regards
D.

Hi Daniele
If you are threading the conductor through the PVC you might try using the 3cm wide copper tapes sold as slug deterrents. This gives you a relatively good surface area and takes advantage of the skin effect to give a very light structure. It is awkward but not impossible to feed it through a narrow tube. The corners are the problem. The peelable backing should be left on. However it is not particularly cheap. Regards John G0UCP

For this kind of amplifier, there will be little difference because of the high-impedance input. Whatever you can thread through the pipes will work the same way.
In case you will upgrade the preamp to a low-impedance input, thicker conductor may help somewhat. By thicker I mean anything more than 18AWG or cheap RG-59 cable.

73, Mike

From: Tom
Topic: 8637 Message: 8637

I live in an apartment. I'm looking to find a frame that I can use to wind various loop antenna designs.

I'm looking for a frame that would allow me to have 4 sides, each side no shorter than 36 in or bigger than 40 in.

Does anyone know of any supply sources that sell loop antenna frames?

I could build my own of course but I HATE woodworking.

TNX to all who respond.

Tom

Tom - you can still build your own and continue to hate woodworking by building a frame made from PVC tubing. The variety of connectors available make almost any shape possible, including a nice stand. All you need is a hacksaw, some PVC glue and a tape measure!

A square loop of 100x100cm is 4m round. You do not need a pre-amp!!

12m wavelength (8MHz) will be around the highest frequency you can reach at this size. Depending on the input capacitance.

At 8Mhz (1/3 lambda) you have no need to worry about your wire efficiencies unless you are going down towards the top bands. You can always add more wire in parallel through the tube increasing its efficiency each time, n/1.

I should have been more explicit. I don't want to build ANYTHING, be it plastic, metal, wood, buffalo horn...nothing!

I want to buy a pre made form. "Back in the day" if you wanted to wind your own coils you could use toilet paper roles, dowl sticks, oatmeal boxes...anything. OR...you could buy pre made coil forms.

I just thought there might be a maker of loop antenna forms. I guess not.

Thank you all anyway.

How about picture frames, boxes, milk crates/storage containers ? These can be used as loop antenna forms although they are not round. The "radio waves" being captured are not particular as to the shape of the "net" being used.

I have a dual 10 turn loop (so I can series/parallel the two). My loop wire is AWG22 fed thru a small choke balun core to a 2 stage homebrew 2N5109 AMP. I can remotely series or parallel the two loops with a relay.

Built my frame out of military fiberglass masting sections epoxied into a PVC 4 input connector. It was just a bit loose so I drilled the connector and fiberglass and inserted some self tapping screws then applied the Devcon epoxy down and around in the small gap then tightened up the screws. This is the pic of the loop frame without the wire support end pieces. The loop frame is 4.5 feet per side (X 4 sides = 22 feet for one full turn). So 10 turns = ~ 220 feet.

I works well with my Kenwood R5000 and my Rycom 6040.

Sorry, the loop frame is 5.5 feet per side, for a total of 22 feet circumference.

I have some additional pictures of the loop wire supports which I will post, if you are interested - each support is just a 3/4 pvc tee fitting with 5 inch pvc stubs on each side and secured in the fiberglass mast tube with 3 evenly spaced sheet metal screws. My first attempt was to drill holes and thread the wire thru...a dismal failure. Then I decided to try a hacksaw and make notches about 1/3 of the way thru the pipe. The AWG 22 wire is pulled around the outside of the pvc and pressed down into the notch. The width of the cut (thickness of the hacksaw blade) is sufficient for a tight fit of the wire and it is firmly held in place.

That worked out pretty well.

The driveway (300 + feet in length) is more impressive at night with the bollard lights on. The past few winters, however, have made me grateful for my snowblower.

And if you are impressed with the driveway, my 570 foot free-floating delta loop @ 70 feet would send you into a tizzy.

Check out my page on QRZ.

Break a leg...OOPS, I see you've already done that

If you have a cheap radio or it has a high impedance input then simply wrap your wire around a cardboard box. If you want to @up@ it's Q you can tune it with a variable capacitor.
Enjoy the fun.

by the way your email address DOES bounce.....?
I was going to send this off list, but since I can't
I'll have to pose here

in Google if you enter:
"Michael Thompson" loop antennas

the 6th links says:

TheRadioBoard :: Search
May 5, 2011 ? Hello All, Very Happy My name is Michael Thompson. Just letting
all that may be interested in a Tuned Loop Antenna for your radio project, ...
christopher.theradioboard.com/rb/search.php?search_author... - Cached

click on the cached link
http://tinyurl.com/5s52r6x

so he posted back on May 5, 2011
that he was still actively making antennas

you might become a member of that board
then try a private message to mltube

if that don't work
then he either doesn't want to respond
or perhaps is having problems of his own
computer, health, new girlfriend keeping him busy......
and for some reason can't respond?
:-)

good luck

GB & 73

8657. Anyone used a PanCake Coil as a Loop antenna?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-07-13 19:59:22 UTC
From: w9ifz
Topic: 8657 Message: 8657

If one is building a magnetic loop antenna it appears the use of a pancake coil would have a better magnetic field pattern.

Wonder what the pros and cons of using one. Any references?

thanks, Stan AK0B

8658. Loop Antenna Components For Sale

Date: 2011-07-13 20:20:10 UTC
From: AlfredR
Topic: 8658 Message: 8658

I have two complete sets of Loop Antenna components for sale. Each consist of three items (1) 12VDC Power Supply (2) Antenna connector module (3) Power unit module which connects 12 VDC and Antenna connector module. Both of these sets are brand new. They were built by Mark Bauman KB7GF of College Place WA. I purchased them 7 months ago and am not able to use them due to health problems at this time. I owned two previous models of these antenna's from Mark and they are great for LW/MW/SW reception! All you will need is a framework of wood or PVC around 3-4 feet and one or two turns of wire, depending on the frequency you are interested in. Asking $50.00 each plus $7.00 shipping. Photographs and further information available. Al Rugel Yucca Valley CA W6JHO

Topic: 8665 Message: 8665

2 videos Tecsun PL-380 using a 30cm diameter loop in place of the ferrite antenna and advantages

Hello friends,

After so much time trying to make time, I finally got
do 2 videos Tecsun PL-380 instead of using traditional antenna Amidon ferrite type 61 7.5 ", a homemade loop 30 cm in diameter with cardboard structure used in shoe soles, easily found in bookstores and for shoe making.

This cardboard, to be directed to the manufacture of shoe soles is very flexible and resilient and therefore the circumference needed for the circular loop antenna does not lose so easily, which allowed me to put the Terk AM loop 1000 even within this antenna to obtain the best possible signal and also noticed that the Q is very high as the circles are closer to each other.

With the permission of the moderator, here are the videos and also a link to my homemade antennas:

www.youtube.com/watch?v=NqXDV410iFc -> video made in Curitiba Tecsun the PL-380 loop antenna with a diameter of 30cm in capturing the Radio Gaucha 600Khz and canceling an interference with the Terk AM 1000 puts it in this loop. Uptake was much stronger than with the antenna Amidon ferrite type 61 with 7.5 ".

www.youtube.com/watch?v=y4j7sHwmoPM -> video made in Curitiba Tecsun the PL-380 with the same antenna picking up Radio Eldorado Criciuma, much stronger than with the antenna of Amidon ferrite type 61 with 7.5 " .

www.flickr.com/x/t/0102002/photos/11973886 @ N06 / -> photos of my antennas

I'm listening a lot to post delayed.

73'sa all and thank you for this opportunity to publish my experiences really crazy, based on what I see so many do.

Milton,
Curitiba / PR

You have to make a mechanical connection to the frame. I mounted the cap to single sided PC board and connected one end of the loop to PC board using a ring terminal soldered to the loop wire. You can get ring terminals at the shack. Look at all my atenna photos.

From that top view - hook one side of the loop to the left lug. Hook the other side to the frame.

If this is already in a radio - whatever you do - do NOT hook the loop between the two lugs. Results would range somewhere from non-operational to downright potentially catastrophic in a tube unit!

If you are making a standalone box loop antenna, you may or may not hook the two sections in parallel to get more tuning range out of the loop. A bit of experimentation is sometimes called for ----

8689. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-10-01 14:51:45 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 8689

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#2. * Torus Tuner 27" Loop Antenna (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

DXers Tool Box - DIY - Tuned Loop Antenna
The DXers Tool Box "How To Build" a Tuned Loop Antenna = How can you vastly improve your Medium Wave reception? The antenna consists of an LC (tuning) circuit formed by the air-core loop and a tuning capacitor.
http://www.geocities.com/SunsetStrip/Underground/8585/loop.html

Embrodary Loops
While these loop are for crafts, they can be a craft of art for improved AM radio reception!
http://www.craftking.com/crafthtml/embroidery_loops.htm

Hard Core DXing
Here's what nordic dx has to offer in their discription of loops in this website
http://www.hard-core-dx.com/nordicdx/antenna/loop/index.html

K5DKZ - Three Foot Box Loop Antenna Kit
Complete Parts and Plans for a 3 Ft Box Loop Antenna "Kit" ~$85+SH
http://www.k5dkz.com/4loop1.html

KIT -by- MTM Scientific, Inc. -for- AM Radio DX Loop Antenna
KIT =//= Designed to Build an AM/MW Radio DX Loop Antenna =//= Offered by MTM Scientific =//= Deluxe Loop Antenna Kit: Includes ALL the Hardware for Building this AM/MW Radio DX Loop Antenna.
http://www.mtmscientific.com/loop.html

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

W2BRI Xmit Loops Contributed by n3hkn
Ham Radio xmitting loops. Detailed plans and reports from Hams experiences. Typical cost is $50 for pipe, capacitor, motor.

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-10-06 12:38:10 UTC
From: Bruce Carter
Topic: 5136 Message: 8691

Good resource, but some of the links are way out of date - I even saw a Geocities link on there!

My loop antenna stuff is now at:

http://www.earmark.net/gesr/loop

And I have to admit - some of my links are way out of date, too. But at least the good people at earmark have lent me a reliable hosting site.

I didn't see the PIXEL LOOP listed anywhere. Check it out at ----

http://store.xmfanstore.com/pixel-technologies-magnetic-loop-antenna-pro-1.html

After buying the first one at its introduction in Dayton in 2010, I got another one for a second remote site. Nicely made loop, made and sold in the States.

> > TL Loop Receiving Antenna 10 KHz - 30 MHz
> > The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

8693. MFJ1788

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-10-10 19:40:34 UTC
From: Steve Roberts
Topic: 8693 Message: 8693

My MFJ1788 has arrived after a wait of 6 months and 3 days (Ordered April 4th).
Out of the box it looks good and the manual seems more than adequate.
Now the fun begins ~ erection and testing

Regards,
Steve Roberts VE3LEH

Subject: [loopantennas] MFJ1788

My MFJ1788 has arrived after a wait of 6 months and 3 days (Ordered April

4th).

Out of the box it looks good and the manual seems more than adequate.

Now the fun begins ~ erection and testing

Hi D
There is a review on eham.net if you can't wait for Steves' review - seems more people love it rather than hate it !

http://www.eham.net/reviews/detail/2992

Thanks,Steve...I have read the reviews on both the MFJ 1788 & 1786 models on eham.net reviews a few times over and also the G4TPH website on mag loops.The more I hear about them the better.You are right,the majority of reviews on this product have been very favorable along with the Alex Walkham loop.73...W7KB.

8697. MFJ1788

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-10-12 21:35:55 UTC
From: Steve Roberts
Topic: 8693 Message: 8697

* My main column is 1-3/4" diameter thick wall aluminum but MFJ1788
only accepts 1-1/2"diameter so decided as this loop is partially directional
to introduce a new rotor that I had in stock for some time..
* Quick trip to metal supper market and obtained 1-1/2"diameter thick
walled tube stub length to go in top portion of rotor. Squared the ends in
the lathe and chamfered ends.
* The first problem (and hope the only one) to come to light was that
the hole centers of the antenna clamping hardware did not match the threaded
mounting holes in the loop body. With a suitable carbide end mill in the
milling machine elongated the holes and rectified the problem. This could
have been done with a round file but there are twelve holes to rectify and
it would have been tedious by hand.
* Assembled rotor to main pole column and assembled loop antenna to
the rotor using the new stub tube.
* Raised the assembly (wobbly as I am old and weak) with column end on
ground into main clamping hardware of bracket.
* Wired rotor (70 feet from house)
* RAIN STOPPED PLAY!!!! Will wire antenna and push column up into the
air on a sunny day.

From: vtnn43e48073
Topic: 8698 Message: 8698

I have a Pixel loop that I want to get up before the snow starts to fly. Since I need a light duty rotor to turn it I was wondering what is considered to be a reliable one to buy? Took a look at the reviews on eham and there are not a lot of TV rotors available anymore and the Channel Master 9521A gets pretty bad reviews.

So if you were to buy a new TV type rotor which one would you suggest?

Hi, I purchased a Channel Master model 9537 and put a MFJ1788 loop on top of it. It is 70 feet from the house and works perfectly. Mind you the MFJ1788 is not very directional but more about that later.

Hello Bill,
No tower involved Bill (I had to give up tower and yagi antennas 4 years ago when we downsized, I got old!). The MFJ1788 is pipe mounted on a garden shed and is 16 feet up in the air. I have another 4 feet sticking out bottom of bracket so with help I can get it 20 feet up in the air.
I have constructed SM0VPO Harry Lythall 80 meter 5 turn loop antenna and ready to test this coming week.
I can send you photographs if you so wish.
I worked in Chicago back in 1965 on loan from England for a very large press company, enjoyed that time.
Cheers Steve Roberts VE3LEH

Hello Sam,
I have attached two digi pics of the 5 turn loop. I have to add the 1/2 turn transmitting loop and build the variable capacitor with motor gearbox. I hope to test this next week.
I have also attached the picture of the MFJ1788 loop mounted on my garden shed. This is a hard antenna to work with as its tuning is so narrow. I am learning some tricks and hope to improve.

Hello Dennis,
I am a complete beginner relative to loop antenna's but I tend to go overboard every time I venture into new territory and this is the case with this project!
Per your request I have attached two digi pics, one shows the 5 turn loop to which I have to ad a 1/2 turn transmitting loop. The other digi pic is the build of the variable capacitor with the motor and gearbox together with the waterproof box.
Also I attached a picture of the MFJ1788.
I work with an Icom 756PRO2 which has 100 watts HOWEVER the tuning of the MFJ1788 has to be done at low power 1 to 20 watts. I find the tuning frustrating so far but hope to learn a few tricks. The problem is I am used to cruising the entire band using Yagi and when one finds a station just responding right away. Not so with a loop antenna as the tuning is so narrow and you can cruise to receive but you can not transmit on what you find until you have retuned. Mind you for an antenna only 36" in diameter I suppose one can not complain.
I have not yet learned how to upload pictures so sort of hope these go out to others at the same time.

Thanks,Steve for your input...Yes,patience is in order here tuning the loop antennas,sort of like working QRP.I guess that is why it is called a "Hi-Q" loop antenna with it's narrow bandwith.This should also help to eliminate some adjacent interference working near others on the bands and being somewhat directional it will also help on the receive side.I do though,like the fact that one can push up to 150 watts into it,making it an efficient radiator.73....Dennis W7KB.

Hello Dennis,

I am a complete beginner relative to loop antenna's but I tend to go

overboard every time I venture into new territory and this is the case with

this project!

Per your request I have attached two digi pics, one shows the 5 turn loop to

which I have to ad a 1/2 turn transmitting loop. The other digi pic is the

build of the variable capacitor with the motor and gearbox together with the

waterproof box.

Also I attached a picture of the MFJ1788.

I work with an Icom 756PRO2 which has 100 watts HOWEVER the tuning of the

MFJ1788 has to be done at low power 1 to 20 watts. I find the tuning

frustrating so far but hope to learn a few tricks. The problem is I am used

to cruising the entire band using Yagi and when one finds a station just

responding right away. Not so with a loop antenna as the tuning is so narrow

and you can cruise to receive but you can not transmit on what you find

until you have retuned. Mind you for an antenna only 36" in diameter I

suppose one can not complain.

I have not yet learned how to upload pictures so sort of hope these go out

to others at the same time.

Hello,Steve...I was wondering if you could offer your own review of the MFJ-1788 mag loop antenna...Does this loop work well for you mounted at this height above ground?.. And the power level you are running it at?...I have been doing some recent research on the MFJ-1786 model.I have read some great eham.net reviews on both models and was curious of your findings.73...Dennis Reagin W7KB.

Steve,

This got my attention, "SM0VPO Harry Lythall 80 meter 5 turn loop antenna and ready to test this coming week."

In time let us know about that one. I have yet to install my home made dipole for 80/75M, old, lazy, sickly and too many irons, shooting club, but will get it done. I'm still studying my ARRL book, the net sites and dealing with family matters that never end.

Thanks.

Hello Jim, Hi Group,
Well thank you Jim as I think I have uploaded two digi pics, one of the 80/160 meter 5 turn loop and the other of the variable capacitor with gear motor gearbox being assembled. Perhaps you would be good enough to confirm that I did indeed succeed???
The MFJ1788 is working wonderfully well today on 10,15 and 20 meters in receive mode. Transmitting works but it is oh so slow tune and respond to a calling station. I will have to work on being much faster somehow. It takes a minimum of 45 seconds to tune for transmit and that does not sound like much but it is.
Cheers

Hello Zack,
Sorry my fault I turned controller upside down and the drive plus controller number is 9521A (for 110 volts). Nicely made unit and an easy installation. I put it to good use this weekend to cancel out hash while operating the contest. The MFJ1788 itself is not very directional but the rotation does eliminate interference thus the selected signal is easier to hear.
Cheers

8720. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-11-01 16:18:27 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 8720

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#2. * Torus Tuner 27" Loop Antenna (Passive)
> - - - website gone
>

#3. * Select-A-Tenna Model #541M (Passive)
> - - - website gone
>

#4. * Terk AM Advantage Loop Antenna (Passive)
> - - - http://www.ccrane.com/antennas/am-antennas/
>

#5. * RadioShack AM Loop Antanna # 15-1853 (Passive)

>

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

K5DKZ - Three Foot Box Loop Antenna Kit
Complete Parts and Plans for a 3 Ft Box Loop Antenna "Kit" ~$85+SH
http://www.k5dkz.com/4loop1.html

KIT -by- MTM Scientific, Inc. -for- AM Radio DX Loop Antenna
KIT =//= Designed to Build an AM/MW Radio DX Loop Antenna =//= Offered by MTM Scientific =//= Deluxe Loop Antenna Kit: Includes ALL the Hardware for Building this AM/MW Radio DX Loop Antenna.
http://www.mtmscientific.com/loop.html

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

W2BRI Xmit Loops Contributed by n3hkn
Ham Radio xmitting loops. Detailed plans and reports from Hams experiences. Typical cost is $50 for pipe, capacitor, motor.

> Basic Wire Back Yard Loop Antennas
> Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

> TL Loop Receiving Antenna 10 KHz - 30 MHz
> The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Please don't do that. If you have something to say, don't do so by responding to something unrelated.

Start up a new email. If you reply to a post, even if you had changed the subject line, Yahoogroups still attaches it to the original thread.

8729. Advice please on 10w tx/rx horizontal loop for HF Amateur use.

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-11-13 13:48:58 UTC
From: dj_philonline
Topic: 8729 Message: 8729

Hi, I have started using loops since moving into a new qth in a deep valley town in Northumberland with lots of overhead domestic 240v and telephone cable networks making HF work nearly impossible, my vertical loop which is big enough (6m x 3 in a delta config.) to cause a stir with the elderly locals is great for 20 to 10m bands but with 5w from my FT-817ND the tuner losses are so great on 40m it is hard to get a good swr reading, I have come up with a plan to put a horizontal loop just inside the top lip of my plastic guttering which surrounds my semi-detached house. Looking for 40m and 80m work on this antenna.
Questions
1: would the loop coming through the loft at the house attached end reduce its performance much?
2: would the 4:1 balun be better located in the loft or outside at the unattached end of the house?
3: would I be better having it as a horizontal dipole centre fed at the unattached end of the house and coming back on itself around either side of the building and not feeding into the loft at all?

I hope these questions are understandable or I will have to try and do drawings and that will not be good, I would rather stick to the loop idea if possible as the reduced noise floor level is fantastic compared to all other types of antennas tried at this location.
Hope somebody can advise.
regards
Phil M6MRP

8730. 2 element 30 meter magnetic loop beam?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-11-13 20:14:59 UTC
From: Brian Burns
Topic: 8634 Message: 8730

Hello All,

Anyone ever heard of someone’s trying to build a two element beam from a couple of magnetic loops?

I got the idea for a 30 meter version the other morning, and try as I do to forget it, it won’t go away! No doubt the problem with such a lash-up for most bands would be having to do synchronized remote tuning of the capacitors for the reflector and driven element.

Virtually all the 30 meter CW activity that I hear is in the lowest 25khz of the 50khz wide band. It might be possible to tune the two loops for minimum swr at 10.112 mhz, and make no attempt to re-tune the antenna for small frequency changes.

I would appreciate any input on the idea, especially to have someone shoot it down so that I can stop thinking about it (;->)…

Cheers,

Brian Burns

The loops would have to be in the same plane and spaced about 12 feet
apart. you could feed them both wih proper phasing ot have the second as a
parasitic element.
They are too small too space them broadside as that is the null space.
perhaps spacing one loop 1/8 wave in front of a plane reflector will do the
same as a 2 element beam and focus all the radiation in the direction from
the reflector.
let us know your results.

Brian,
Many years ago in Rad Comm's Technical Topics there was
an item on a Racal system used by the military where a self-supporting
driven loop and many parasitic ones were used by just standing them in line,
a bit like traffic cones.
Someone may remember more about it.

I would think that getting the proper electrical length (tuning) for the parasite would be a nighmare. Then it seems that for most useful arrangements, Rrad of the drive loop could drop even lower as a reuslt of mutual Z coupling. Finally, given any moisture and the resultant detuning would throw the whole thing off again.

Your idea is analyzed in many of the standard professional/academic engineering antenna books and applied to practice as documented in several IEEE papers over the years.

Topic: 8736 Message: 8736

Good evening all,

Using rjeloop3 (downloadable on the "zerobeat" page), I modelled a reasonably performant RX single-turn loop for LW, centered on RXing onthe 2200m Band (137kHz).
It is made of diameter 16mm copper tube, is square in its form with side lengths of 250cm (fixed antenna). By changing capacitors networks, I could tune it on our future 472kHz band, and possibly even on 160 meters.

Capacitors values given are:

For 137kHz: 135723pF.
For 475kHz: 11279pF.
For 1825kHz: 752pF.

But the problem I have is with impedance matching: For 137kHz I've got to cope with 3,8KOhms, on 475kHz with 24,5KOhms and on 1825kHz with 180,6KOhms !!!

Do I read something badly ? Aren't loop antennas known to be low impedance antennas ?

If not (the numbers I gave you being correct measurements...), how do you cope with such impedance mismatch ?

Friendly,

de F8GRY/Ben

8738. Does a loop have to be resonant?

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-11-14 22:15:40 UTC
From: w9ifz
Topic: 8738 Message: 8738

I want to build a loop antenna that I can connect to my 50 ohm input shortwave receiver and use it for HF (1.8 MHz - 30 MHz).

I guess I will have to tune it. But would really like it just to be broad band. So if I tune it what would be a reasonable Q for the coil?

I am thinking along the lines of a loop that is 12 inchs to 18 inches square. Not magnetic.

Have done several web searches but guess I need better search words.

any suggestions

After reading a bit further, such high impedances seems to be a common thing for antennas this type. My mistake...

About lowfer band: 99516pF @ 160kHz es 70571pF @ 190kHz

Which makes quite a large capacity range... Probably needing a switchable capacitors network.

And, little hope of getting something from lowfer band here in France. What kind of maximum ERP do you enjoy in this band ?

Plus, I'm relatively close to our France Inter LW broadcast transmitter, which has 2MW (1MW at night) on 162kHz... Nulling it with the loop will probably not be enough I fear.

Thank you for your reply. In the US the part 15 law states that lowfer transmitters can only have 1 watt of DC input and an antenna no longer than 15 meters in overall length including feedline.

The lowdown website is the longwave club of America. It is a good resource of low frequency information.

Stan,

No.

A simple untuned 12 inch by 12 inch loop will pick up RF energy and you should expect to be able to hear signals with your receiver with it. There is a natural resonance for this loop which is greater than 50 MHz. The coupling means and transmission line used may tend to lower this resonance. I have a 6 ft diameter untuned loop made of copper 3/8 inch diameter water tubing I had on the roof for a couple of years that worked quite nicely. As I recall, the natural resonant frequency was measured at about 50 MHz. A major advantage was the reduction of powerline noise which was significantly reduced. Used a minicircuits 1:4 transformer at the ends of the loop to a 75 ohm or 50 ohm coax to the shack.

Alex

I used a 4ft piece of RG-58 coax cable plugged into my FT-817 with an alligator clip at the end of the center conductor hooked to the ground lug on the back of the radio, forming a loop. The shield end is unconnected.

Just walking around with this "antenna", finding the place and orientation in the house where the coupling to the powerline noise is minimal. The signal is fairly low, but because I can null the noise, this setup gives me much better S/N than a wire inside the house.

This loop is definitely magnetic, because the center conductor inside the cable is electrically shielded and is much shorter than the signal wavelength. The definition of the magnetic loop is that it is sensitive to the magnetic component of the wave.

73, Mike.

The lowdown seems indeed to be a nice source of info. I'll have to subscribe soon.

How about 472kHz in the US ? Does as little amateur think about QRV as in France ? The WD2XSH experiments having been a real success (some of them audible in my QTH, and QRSS "OOO" copy !), I hope trans-atlantic QSOs will soon be regular...

Personally, 137 es 472 are my top priority, as a newly licensed Ham. Hope CU later on the grabber or in 600m CW !

Hi Stan,

While my contribution is short on theory, it works very well from the bottom of the broadcast band to about 14 MHz without any tuning or preamplifier. With a preamp at the feedpoint the loop will work well at higher frequencies as well. I use my two loops all the time on the BCB and frequently use them to receive while operating from 160 - 40 meters.

Hi Harold,

The loops are connected to the RX ANT inputs of a Flex 5000A and a Kenwood TS-590S. Previously, they were used with the RX ANT input of an ICOM Pro III. The Flex and Kenwood use an internal relay to ground the RX ANT input when transmitting, so there is a built-in safety factor there. I do not know if the Pro III grounded its RX ANT while transmitting.

With a second RX option (which I do not have) I am unsure how that is handled, but since the Flex allows full duplex operation when the option is installed, it does give some pause for thought.

No ill effects have been experienced and I do run the full 1500 watt power level frequently. There is about 50 feet of separation between the E-W loop and the transmitting inverted vee, and about 100 feet of separation between the N-S loop and the transmitting antenna. I have not lost a diode yet, so it seems to be enough. That being said, it seemed prudent to wind a 1:1 transformer for isolation purposes, with back-to-back diodes installed, to be used right at the RX ANT input of the Flex and the Kenwood. It's probably over-kill since the original diodes out at the loop feedpoint have never failed, but it was cheap insurance!

73,

Rob W1AEX

It does not have to be resonant. But a broadband loop will lose 40 to 50 dB of gain - or more.

Well, the next logical step is to connect an amplifier to it.
This is not as simple as it sounds, but this is what Wellbrook, Pixel Tech. and others do.

direct link:
http://www.qrz.com/db/M0ZSA

The slinky types I bought have a DC resistance of several ohms. I did not get around to use them in an antenna. For a dipole this might not be too much of a problem. But with a magnetic loop the radiation resistance is very low. I can imagine the additional slinky loss makes this a far from optimal TX antenna. Getting to SWR 1:1 will be easier with a lot of loss too.

Can you measure the voltage on the Jennings capacitor? I doubt if it will reach the multi-kilovolts a high-Q loop usually has.
One other thing that you could do is to measure the loop bandwidth. If it is not narrow, this will tell you something as well.

Cheers,
Joop

8757. HELP

From: Steve Roberts
Topic: 8502 Message: 8757

Hello Group,
Yes I know this is a loop group and I do have one but it is so slow to tune decided to have a backup.
I have installed a 43 foot vertical and no problems with that item.
I purchased a MFJ2910 80/160 meter high efficiency matching network that is hose clamped between the actual 43" antenna and the support pipe (in the ground). No structural problems there, it all fits perfectly
Now comes the problem, the tuning instructions (this is done with the cover off exposing the relays and coils). With regard to the 160 meter they do not illustrate or mention which coil to tune (using a clamp tap provided). I am guessing it is the longest coil. The instruction manual says the (flexible) tap will tune the place on the band and the shunt tap will adjust the impedance at resonance. I see no shunt tap?
Now with regard to the 80 meter coil which I assume is the shortest (of the two coils) they again describe the tap but on this coil I have three flexible clamp taps.
A call to technical support at MFJ only gets me to voice mail and no call back so far. Probably my location in Toronto area is a problem for them.
Does anyone have experience with the MFJ2910. I can post close up high quality digital photographs if it helps.
Any help on this matter will be sincerely appreciated

I really like the idea of the Wellbrook and Pixel broadband-preamplified loops. Unfortunately, it's unclear to me how well they do with moderately weak to borderline signals on 160 - 40 meters. The video of the Pixel loop demonstrating reception on the broadcast band is impressive in its SNR performance, but I wonder about the small capture area of the untuned loops on those lower amateur bands.

Has anyone found a video that demonstrates performance on the lower ham and shortwave bands? I have not seen anything on YouTube showing this. Maybe someone who has one of these would be willing to make a brief video?

Thanks,

Rob W1AEX

8759. Full wave loop for 10mtrs

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-11-22 15:44:57 UTC
From: Richard
Topic: 8759 Message: 8759

Hi Guys, a long while since my last posting.
If you look at my little antenna farm on qrz.com, this might make sense.

I've now got a vertical rectangular loop running between the 1st & 2nd director of the 6mtr yagi , up to the grp cross boom supporting the 2mtr and 70 cms antennas, the back down to the 6 mtrs yagi between directors 1 & 2.
I've used the formula of 1008/freq,
which for 28.5 MHz came out at 34'
So far I've had to add another 2 mtrs to the length to get it back down to 30 MHz as it was resonant at 36 MHz.
The extra length has had to be coiled on a 19mm GRP rod as I'm out of space.
I would have expected capacitive loading making it shorter, not longer, not the opposite .
My antenna experience is all VHF upwards, I always thought loops were tolerant to surrounding antennas etc.

Any ideas ?

I also liked the idea of these antennas and purchased Pixel about 1 year ago.
Mainly tried to use it for 160m, several times for 80m. Till now my 1/4L TX inverted GP works better for RX. I don't have video or even didn't make a complete scientific comparison between these two (TX vertical and Pixel loop installed on a top of the tower with "Christmas tree", overall height above the ground- 45m) but my 30 years experience says that COULD BE that the loop performs slightly better only for relatively short distances (up to 3000km). I never ever heard with it something, that I didn't hear with TX antenna while opposite is quite often.
I must admit that Pixel's loop's preamp is really good: when I already hear something- it sounds extremely clear (it still has gain head over!), the filtering and distortion sounds similar to good DSP:-) I'm planning to use this preamp for some other RX antenna.

No loop will cover that much spectrum without swapping out the coil. This is the closest antenna that will meet your needs.

Since commercial loops from Pixel Technologies and Wellbrook Communications have been mentioned recently, I thought I'd post a link to my review of the RF PRO-1A and ALA1530, which some may not have read previously.

Look in the "Links" section of the group for the article titled "The Pixel Technologies RF PRO-1A and Wellbrook Communications ALA1530 Active Loop Antennas Compared".

This detailed comparison used the markers feature of the Perseus SDR receiver to measure S/N ratios of many signals heard on both antennas from longwave through 13 meters. The summary data is presented via bar and pie charts. Original Excel source file and comparison MP3 audio files are available for download from a link within the article.

Thanks to Colin Newell of DXer.ca <http://www.dxer.ca/> and Mika Mäkeläinen of DXing.info <http://www.dxing.info/> for hosting this review on their web sites.

Well, here's an amplifier that is capable of better performance than the Pixel or Wellbrook:

http://www.home.earthlink.net/~christrask/Paper009.html

which can be used in place of the tuner section in this loop antenna:

Building a magnetic loop is simple, but covering that much spectrum is tricky. You will need a substantial coil for 20 kHz, that same coil cant be resonant at 30 mHz. With a large amount of capacitance you could use a much smaller coil but it will be so inefficient as to be useless. You could build taps into the coil hooked to a rotary switch. Either way it will be tricky and a study in patience. Here's a simple magnetic loop calculator, just plug in the numbers and tri a number of values.

Hi Chris,
I can't get the amplifier link (paper009.html) to work,
can you help ?

Hi,

I have been wanting to build the loop described at
http://www.home.earthlink.net/~christrask/Paper009.html

but I have been have not found a source for the Fair-Rite 2861000102 balun core in the US, google search only give me a back order option on a number of component suppliers.

Does anyone know where to buy a small quantity of them also would like to know if there is a place where I can get all the cores for this project ie FairRite 2861000102 , 2843002402 , 2843002402. The paper states that mini circuit transformers can be used for the last 2 cores but I would prefer to wind my own transformers.

You can also use a 2861000202, which is just a little shorter. It and the other cores can be purchased from W8DIZ:

http://www.kitsandparts.com/toroids.php

They are listed at the bottom of the page.

>

And you'll be better off for doing so. The Mini-Circuits transformers are a compromise of size, performance, and cost. The performance suffers greatly.

Have you tried Amidon? https://www.amidoncorp.com/

The Fair-Rite part numbers will have to be translated to "ham radio" part numbers if you look on their web site.

28 indicates it's a multi-aperture core, which is a "BN" designator at Amidon. The next two digits are the core material, 61 for example. This will be a BN61 core at Amidon. Then, the last 4 digits are an identifier of the physical core dimensions and are carried through. So a Fair-Rite PN 2843002402 will be a BN43-2402 in Amidon's catalog. And, you will probably find this particular core identified as a BN43-2402 more often than as a 2843002402 core in construction articles.

If you can't find all the particular cores you are looking for at Amidon's web page, I would also send Amidon an E-mail and ask if they are available as not all their stock is reflected in the on-line pages. Some of the less popular cores may have a minimum purchase requirement though.

Hi Phil all noted , I've put this re[ply back on the list from what I've found.
the formula 1008/f(MHz) is OK when the sides on a quad or delta loop, especially the delta loop if all
sides are approximately equal in length.

However as the side lengths become irregular the length of the overall loop increases to achieve
resonance. On a 10 mtr Delta loop I found a variation of 2mtrs , 6 foot, depending on the shape, the same
with an irregular sided quad, the impedance also changes.

I'm now using a delta loop corner fed with equal sides mounted in the horizontal plane , mounted at
roof height, and it works well.

Now tempted for one for 20 mtrs as I can suspend that horizontally over the top of the roof.

Richard,
I don't follow your answer of variation of 2M, 6 foot for the 10M Delta Loop. What was the length?

Hi Bill
I started with 35' 4" ans with irregular sides that resonated at 34 MHz, adding 6' bought that down but
the vswr was greater than 2.5:1.
I then tried in a diamond configuration which again resonated much higher again around 34 MHz.

After that I removed the loop from the tower and strung it from the house to a support. I found again
that 35' 4" resonated hight in a non equilateral formation , I added about 4' to get it to resonate
@28.5 MHz.
After a bit of restringing to get a delta loop with equal sides, that it resonated at the

wanted
frequency with about 35' and the impedance moved to around 130 ohms. It gives a vswr of less than 1.5:1
with a 4:1 balun from 28.3 to 28.6 MHz

You could scale up my loop described in the ARRL National Contest
Journal 2 years ago (also available at www.n6rk.com). You would
need to divide the range into two ranges, 3 to 6.5 MHz and 6.5 to 14
MHz. For the first range, use only one varactor instead of two.
For the second range, use two varactors in series. Also, the
circumference for the first range should be about 12 feet and
the circumference for the second range should be about 6 feet.
I still have blank PC boards available (see www.n6rk.com).

Easily done for outdoor remote:

http://www.home.earthlink.net/~christrask/Varactor%20Tuned%20Loop%20Antenna.
pdf

or indoor:

http://www.home.earthlink.net/~christrask/Indoor%20Loop%20Antenna.pdf

You'll need two loop elements, one at 1.5m diameter and the other at
0.75m diameter to cover that entire frequency range.

Hi Craig
Have a look at my call on QRZ.com (M0ZSA)
I have had some Technical boffins who have poopoed this antenna without trying it.

They question the radiating ability because of the steel slinky coil, copper would be better in this design but is not practical. All I do know is I have tried many commercial stealth antennas that one can use in an environment were no antennas are aloud and this loop outworks them all. And it can be put together in your kitchen.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

8791. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-12-01 13:21:01 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 8791

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

8792. RE: [loopantennas] Re: Light duty rotor suggestions for Pixel loop

Topic: 8698 Message: 8792

In case you are wondering I am still fiddling with it. The mechanics of the antenna are complete and it is wired ready for the 75 pf variable capacitor. I am waiting for a good weather day and I will temporary rig the antenna and try it out on receive and if all seems in order I will give it a transmit try out at low wattage and proceed from there.
Because the loop (1788) was so slow in tuning I decided to install a back up 43' MFJ vertical antenna 6 to 160 meters as shown on the attached picture. Wonderful results, nearly as good as the yagi beams I gave up four years ago when I moved location.
Cheers
Steve Roberts VE3LEH

Steve,

This got my attention, "SM0VPO Harry Lythall 80 meter 5 turn loop antenna and
ready to test this coming week."

In time let us know about that one. I have yet to install my home made dipole for 80/75M, old, lazy, sickly and too many irons, shooting club, but will get it done. I'm still studying my ARRL book, the net sites and dealing with family matters that never end.

Thanks.

From: Adam E
Topic: 8794 Message: 8794

I am looking for varactor tuning diodes that cover 20 pF to 450 pF, because air variable's and polyfilms are getting hard to find. Plus I am going to build a tuner circuit that will remotely tune my large loop antenna that is in the living room. Part numbers are MVAM108, 109, and anything that would be good for LW/MW and Shortwave Use. Also I have 2 new radios that work great on loop antennas and they are the KA-1103 and S450DLX.

Basically, the only AM radio type varactor you can get now is
the NTE-618 available from Mouser (526-NTE-618). It will replace
the MVAM-109 series.

They are listed as "not recommended for new design", which means they are in danger of being discontinued. They have a couple of thousand left at $2.70 each. I'd get my "lifetime buy" in now before they are gone!!!!

In many cases, this simply means that it is being superceded with
a lead free version. I might also mean that it is being superceded
with a surface mount version. Or it could mean what you said,
the end of the line.

From: kevin asato
Topic: 8799 Message: 8800

The 160MHz weatherband is normally very accessible using a vertical antenna or outside TV antenna. Loop antennas for this frequency are normally a full wavelength of wire; about 64" of wire or about 18" per side. Shortened loops at this frequency are not worth the effort as the loops tend to be lossy.

Search on "quad antenna calculator" for ideas. http://n6ach.com/calc/quad.html is one such link.

A 2 foot loop with 1 turn like a UHF loop antenna will work for a weather band loop at 162 to 163 MHz you will need a 300 ohm to 75 ohm
transformer to connect to the receiver. You can connect a variable tuning capacitor in series with the loop antenna to the telescoping rod of the receiver. Don't worry 50 ohm connections will still work with 75 ohm connections.

MFJ-1786
10-30 MHz Hi-Q Deluxe Loop Antenna

Does anyone have this this antenna, and can tell me what kind of reception they have with it.
I have it and I'm trying to determine if mine is working properly or if it has a problem.

Hi Stephen
I got mine second hand looked like new but would not tune.
After many hours of trying to get it to work, I ordered a new inner loop and board and now it works.
I still think the tuner is a pain in the but.
I am very happy with it now.
There is nothing like an antenna up high.

As I think you know Bill I have the MFJ-1788 Super Hi-Q loop antenna and I have very mixed feelings about it. The reception is actually good with overseas such as Italy etc coming in at 5 and 9 and the 20,15 and 10 meter bands are very quiet compared to the beams I used to have. My reservations are with the transmitting in that it is a slow process to tune it, sort of frustrating. You hear a station calling CQ, you move to the side of him to tune which takes 45 seconds and you move on his frequency by which time someone else has made contact with him.I attach picture. Mine is mounted on a rotor but there again the loop is not very directional.
The end result is that I purchased a MFJ-2990 43 foot self supporting vertical antenna 160-6 meters and this does an excellent job.
I would be willing to sell the 1788 for half what I paid for it about three months ago if you are interested. Shipping would e at your cost.
Cheers

Robert,
No thanks, really, I don't want to deal with something difficult to use or beyond my ability as my TS-2000 manual is now a reference book rather than an unreadable manual. I solicit help is on the Kenwood site. I have a dipole, made up at a ham meeting for me two months ago and I haven't set it up in the yard yet. Lazy me.

eHam.net had extremes of experiences with the loop, meaning some of them have gotten theirs to work for them on Tx. I have a crude square loop of about 6' length hanging above a framed photo next to my DX-398 receiver and it works almost as well as a much longer loop around the office. Tx gets involved for loops and I don't have any experience. It has been a long time since I used an end fed long wire outside for the 398 or crystal sets. II have studied antennas for the last 3 years and loops look like what one needs in a portable antenna or in a cramped space outside or inside the home or attic and even then a long wire or di-pole can be placed in the attic or on the roof and the roof may be where I try my dipole.

I have a PRO-1A bought early this year. It has permitted me to null the powerline radiated hash, something my decades of DXing with every conceivable wire antenna here at my home wouldn't. The combination of it and my Palstar R30A is a winner - and resurrected my hobby. I often run a splitter off it's output so I can compare the sync AM detector of my Lowe HF-150. It is a decent value, chosen here over the Wellbrook due to it's using modular construction and being US-made. I am well pleased with it! See Eham reviews.

Hello,
I have an mfj 1788, I had a few problems with it to begin with and I though it was duff, until I found out the problem was with the coax.
It is also sensitive to placement once that was resolved I'm really pleased with how it functions, especially when you consider its on a desk top in and upstairs bedroom.(based in suffolk uk) I've not tried it on ssb as yet but in digital mode psk31 I have had contacts in Italy on 20 and 40 mtrs at 5 watts. Tuning was difficult to master intialy, tune for noise then fine tune using cw,worked best for me but you may fined you need to fine tune as you move up and down the frequency.
I hope you find this offers some encouragement with yours.

8815. Joe Carr's side-by-side Quad

Yahoo group: loopantennas (2008 — 2012)
Date: 2011-12-23 19:11:06 UTC
From: Brian Burns
Topic: 8815 Message: 8815

Hello All,

I just received my copy of Joe Carr's "Loop Antenna Handbook" from Universal Radio. On page 42 he describes (briefly) the Side-by-Side Quad antenna. It consists of two full wave loops both in the same plane (edge to edge) separated by a quarter wavelength. They are fed 180 degrees out of phase with a 1:1 balun.

There are no other details such as directivity, gain, f/b ratio etc. Anyone know anything about this arrangement, or was it just a thought experiment? There is no mention of it in his practical antenna book.

Cheers,

Brian

From: Ilya Zozin
Topic: 8809 Message: 8816

That's what I wrote few weeks ago in some other thread:
I also liked the idea of these antennas and purchased Pixel about 1 year ago. Mainly tried to use it for 160m, several times for 80m. Till now my 1/4L TX inverted GP works better for RX. I don't have video or even didn't make a complete scientific comparison between these two (TX vertical and Pixel loop installed on a top of the tower with "Christmas tree", overall height above the ground- 45m) but my 30 years experience says that COULD BE that the loop performs slightly better only for relatively short distances (up to 3000km). I never ever heard with it something, that I didn't hear with TX antenna while opposite is quite often.
I must admit that Pixel's loop's preamp is really good: when I already hear something- it sounds extremely clear (it still has gain head over!), the filtering and distortion sounds similar to good DSP:-) I'm planning to use this preamp for some other RX antenna.

I have one as well and am very happy with it. Don't put too much stock in the comparison to the Wellbrook test you see online. I suspect that with the Pixel Pro's deeper null and using rotors on both antennas to optimize for each frequency, the Pixel Pro will hold it's own.

From: thinkdx
Topic: 8811 Message: 8824

It's very possible that the newer "B" version of the Pixel loop is the competitive product to the Wellbrook loop that I had hoped the original one would be. My comparison article was based on the first RF PRO-1A model. Also, the testing of each loop's nulling ability using my antenna rotor etc. was out of the scope of my review. It was enough effort by itself to methodically capture and calculate S/N ratio data for each antenna with the Perseus SDR (ie, determining the best loop on the desired signal without the added variable of nulling unwanted signals or noise).

73,

Guy

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

8827. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-01-01 13:21:53 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 8827

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Happy New Year Everyone,

I wanted to share this with everyone who uses varicaps I found out that you can use a ordinary diode such 1N5822 which will put the capacitance up to 490 pF, great for LW and VLF circuits. I have to see what I have in my junk box. I discovered varactor diodes when I was building a SR-2 short wave radio receiver kit from Ramsey Electronics.

Great and useful research!

Your work has opened my eyes to another issue. I use 1N914's to protect my RX320 RF input against lightning (lots of that in Arizona). So I'm gonna have to find the capacitance of these guys is presenting too much reactance to the input.

Thanks again Adam!

From: shibukiau
Topic: 8809 Message: 8836

I liked my first one which I bought at it's introduction in Dayton a couple of years ago, that I got another one for my remote HF station as a RX antenna. The first one is in the attic as a monitor and the second is outside.

The second one seems to be better as it appears to have less noise, it is however much better mechanically in terms of weather proofing.

Antenna really digs out the weak signals in a noisy environment particularly when compared to a vertical antenna.

For the money they are a great RX antenna, very hard to beat. Low noise and decent rejection off the side.

I'd like to get another one for my station here in OZ but the shipping costs are a real killer!!!

Cheers!

From: Jeff Arnold
Topic: 8803 Message: 8837

Finely got a chance to play with the mfj-1786 loop. Works surprisingly well. Except I can't get the swr down below 2.1. I am going to try adjusting the inner loop to see if the swr will go down. As far as tuning I would rather here the noise increase than tx a signal till the loop controller found the lowest swr which it did not find to often. What works best for me is while tuning the loop no tx on the icom 756 pro 3 watching the spectrum scope. I can dial it in really close every time by watching the spectrum scope. I can see if you don't have a spectrum scope and you don't have much noise to listen for tuning might be better to tx tune. Still playing with loop but I think it's going to be a great little antenna.

Topic: 8803 Message: 8838

I forgot to mention the receive on the mfj-1786 noise floor was about 4 to 5 s units lower than my 20 meter horizontal attic dipole which reads about s9 noise all the time. The snr on the loop is good enough I can make out what people are saying and they can here me. On the 20 meter dipole all I here is static when I switch to the loop I can here people. It's doing what I wanted here at the antenna restricted condo.

Thank you,
Jeff

On Jan 9, 2012, at 1:17 AM, Jeff Arnold <al3q.jeff@...> wrote:

> Finely got a chance to play with the mfj-1786 loop. Works surprisingly well. Except I can't get the swr down below 2.1. I am going to try adjusting the inner loop to see if the swr will go down. As far as tuning I would rather here the noise increase than tx a signal till the loop controller found the lowest swr which it did not find to often. What works best for me is while tuning the loop no tx on the icom 756 pro 3 watching the spectrum scope. I can dial it in really close every time by watching the spectrum scope. I can see if you don't have a spectrum scope and you don't have much noise to listen for tuning might be better to tx tune. Still playing with loop but I think it's going to be a great little antenna.

RS coponents are selling dualk varicaps sanyo SVC389.
earlier i sadid element14.
here is the Singapore link http://singapore.rs-online.com/web/p/varactor/0546452/
perhaps local RS Componments can check and get for your neeed also
they are cheap at 25 lot costing only sing$0.32 each, that too a dual.

I've got a Kiwa MW Loop antenna that I want to sell. It's in excellent condition and good working order. Anybody have any ideas about what price I should ask? Bought it years ago, but don't remember what it cost then. Saw one on ebay about a month ago but missed seeing what it sold for.

Harry

You could sell it to me for $25!! Universal Radio web site shows two that sold used for $289 each. The original price for a new one was as high as $440. Jim

Dear Jim,
    I have a universal radio catalog from 2000-2003 stating that the loop antenna sold for $389.95 brand new. Note I have seen these Kiwa loop antennas sell for over 500.00 used on ebay if they were in good condition. I hope this will help you out.

RE; Kiwa Loop Antanna:

I had one and while people might be willing to pay 600.00 for a used one on Ebay in my opinion they are way overrated. Most of my interest is in LW and MW dx and I compared the 400.00 kiwa loop (what i paid for it at the time) with a 49.95 (what i paid for it on sale) Ccrane twin ferrite loop and the Ccrane was the equal to or better antenna across the whole MW spectrum - IMHO save your money. I wouldn't pay $150 for one, unless of course i was reselling it for 600.00.

I built a 40m horizontal loop in my attic. A regular "Skywave" loop that's installed at the proper height is ideal, but I've had good luck with mine in spite of it being 20 feet off the ground (at its lowest point).

Since the space to install my loop was too small (30' X 30') for a normal loop, I had to distort the shape from a square to a star by pulling the sides inwards and upwards so it's vaguely pyramid shaped. All told, I have about 1.25 wavelengths installed and use it with a directly attached Balun Designs 4:1 balun. Signal path is:

FT-897 - 6' RG-8X -> LDG AT100ProII autotuner -> - 30' RG-8X -> 4:1 Balun -> antenna

The balun and tuner are not optional for this type of antenna.

The antenna has four strong lobes at 40m and the TOA improves as the frequency increases. The propagation pattern changes a bit on each frequency. Cebik's site has an article on star-loops and his models show the capabilities of the antenna pretty well. My antenna deviates from his design by raising the pulled-in center about 8 feet so I could avoid my in-attic heat pump and ducting. I'm sure this affects the propagation pattern, but until I model it, I won't know exactly how. I suspect it's helped it from being a cloud burner since my antenna's so close to the ground.

I'm able to get a 1.3:1 or better match on all bands between 40 and 10m and usually 1.5:1 or better on 6m. I've not used it much on 6m, but I'm able to get out very well from the DC area to Asiatic Russia, most of Europe, Southern South America, South
Africa, Alaska and California, usually on 30 watts.

Construction was pretty easy. I used 8 insulators, some strong line and 14 gauge coated wire. It took the afternoon. The hardest part of the whole job was pulling the coax down into my shack.

Since I didn't want to crawl out to the edges of my attic, I made some supports from PVC on a long PVC pole and pushed them out into the corners and held it in place by screwing the end of the pole to the joists. The business end of the supports engage between the rafter and the joist and keep the wire in place as I pulled it in.

The job is easier with two people, but if you're smart and do a bit of planning, you can manage it on your own. Just don't fall through the ceiling. We have a two story family room and I tred VERY carefully when I was above it.

I've been considering the same antenna, how is it performing compared to your previous? Thats about the limit of the room I have and looks like it might perform well in a limited space.

This is my first HF antenna, so I don't have a lot to compare it with. It worked pretty well right off and most of my QSO's have been DX, so I'm pretty tickled overall.

I find I get stepped on by the big hitters when I'm chasing a pileup, but that's probably not unusual. I got very lucky with the way my house is situated. One lobe points straight into Europe and another sweeps eastern South America. It's interesting to display the QTH of all the QSO's with google earth (I use HRD's logging program to see that). You can see that most of the contacts correlate with the prop pattern.

I've been assuming all along that it has been collectors paying these inflated prices.
However, the Kiwa regeneration control (the Quantum Loop has one too) makes it a better antenna than simple ones like Ccrane. Also, the very sturdy construction helps it to stay stable and maintain nulls. The twin ferrite loop has no facility for tilting/rotating.
In the 1990s I sometimes used a Kiwa MW Loop for trans-Pacific MW DXing and it certainly held its own against Beverages my Seattle area DXing pals and I used at Grayland. In fact, the Kiwa's regeneration feature helps improve selectivity and reduce splatter from adjacent channel domestics (for instance, on reception of HLCA Korea on 972 kHz in the shadow of stations on 970). This is a huge help in receiving the foreign stations. We've moved on to specialty antennas like phased ALA100 loops now though, and the selectivity of current SDR receivers need no help from controls like regeneration.
In the 1994-95 Proceedings of Fine Tuning book, the FT staff and I published Werner Funkenhauser's review of the Kiwa MW Loop. It's available here online via Kiwa's web site for anyone interested:http://www.kiwa.com/proceed.html

Kiwa MW Loop Antenna
Posted by: "Harry" hmholden69@... hmholden69
Sun Jan 15, 2012 7:35 am (PST)

I've got a Kiwa MW Loop antenna that I want to sell. It's in excellent condition and good working order. Anybody have any ideas about what price I should ask? Bought it years ago, but don't remember what it cost then. Saw one on ebay about a month ago but missed seeing what it sold for.

Harry

Harry.I had 3 and sold one to a German collector for $600 plus ship last year and he was very grateful. They are beautiful to look at and beat just about anything I have come across in 50 years.will never be made again.

Used ones are very rare.don't sell it for less.as the old saying goes...try to find one!!

Gary

8862. Kiwa MW Loop !!!!!

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-01-23 09:37:41 UTC
From: brian nsl
Topic: 8862 Message: 8862

Hi,
Following this thread I had a look at the now discontinued model.
it looks very neat.
I have an amount of PVC 5mm wall pipe offcuts from a fume ducting job,
starting at 200 mm dia and up to 600 mm dia, might give the idea a try out
for a MW antenna.
I assume that the ' inner mounted ' box is an amplifier ????
Any owners like to comment please.
Thank you,
72, Brian, G0NSL-QRP.

Dear OM,

To answer your question it is best to go to the website of Jack Smith, K8ZOA, Clifton Laboratories
His website is: http://www.cliftonlaboratories.com/Updates.htm

Download the most recent, excellent and outstanding comparative study, between the Pixel and Wellbrock LOOP

http://www.cliftonlaboratories.com/Documents/Loop% 20vs% 20Final% 20Loop-Final.pdf

Best regards from France

Bernard MALET

From: Bernard Malet
Topic: 8868 Message: 8868

Dear OM and SWL,

To answer this question, which antenna to choose?

The best solution is to visit the site of Jack Smith, K8ZOA, Clifton Laboratories
His website is: http://www.cliftonlaboratories.com

He has just completed a new an excellent, outstanding and long article and comparison between PIXEL / WALLBROCK

Download the new document:
http://www.cliftonlaboratories.com/Documents/Loop% 20vs% 20Final% 20Loop-Final.pdf

From my side I use as an antenna Z1501D completed its fabulous Long Telescopic Whip of 9.5 feet from home Buddipole: http://www.buddipole.com/lotewh.html

Both U.S. companies have robust and efficient materials.

Best regards to you all from France

8869. Terminated Delta Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-01-30 19:24:52 UTC
From: g7aqk@btinternet.com
Topic: 8869 Message: 8869

Over the weekend I tried to build a T2FD antenna. This is basically a folded dipole with a load resistor opposite the feedpoint (Google T2FD for more details). This arrangement can produce a very low SWR across the whole of the HF spectrum. Now my version had too much sag at the feedpoint due to the weight of the feeder, but I thought I would give the design a test to see how well it performed. The antenna pulled in loads of stations across the HF spectrum and showed good SWR on all bands except 12m (this may be due to resonance which is something to be avoided with this type of antenna). The delta loop formation is mechanically much easier to feed than the dipole as the 6:1 balun is closer to the ground. Has this arrangement been tried before? I have not been able to find any reference to a loaded delta loop on the web but am very impressed with the results.

From: Alex P
Topic: 8869 Message: 8870

Neil,

A terminated delta loop has been tried before and there is info in a variety of ant books. Keep in mind that if you terminate with a non-inductive resistor there is a significant amount of tx power that is converted to heat and is therefore not radiated. This is a tradeoff that you make for an increased bandwidth with this kind of design for a lower tx VSWR. For receive mode, this antenna also 'appears' more 'broadband'. Since it's a variation of an H-field ('magnetic') loop, the signal-to-noise ratio should significantly increase by having an immunity to the locally generated E-field 'noise'. The value of the termination will affect this performance. As a side note, until the Santa Ana's blew it down a few weeks ago, I had a 53 foot circumference delta loop on my tower with the horizontal baseline leg at about 48 ft when extended (about 65 ft total vertical length). This version of the loop did not have any termination. The rx baseband noise went from S7-S9 using a formally installed 20 meter ground plane to about S0-S1 (average measured baseband noise of about -132 to -125 dBm) using this delta loop. Best antenna I've had so far for receive mode. Picked up many LW beacons not formerly heard as well as good dx recently on 10 and 15 meters.
Hope this helps.

Alex

Our experience (club) with a T2FD was dismal. Great SWR readings on all bands, just deaf as a post and no output. Could not hear it across town. A great dummy load.

I wonder why it didn't work for you, maybe you were expecting
something different. T2FD is not a "weak signal" antenna, but it works
very well in high noise environments. I've been using a T2FD (mounted
inverted "V" style) for many years. Really serious noise problems here
and the T2FD was the only one of many antennas tried that would bring in
a clean signal. If your location has off frequency noise on top of
moderately strong desired signals, the T2FD is a "second to none"
antenna choice.
Reducing the local noise level -WILL- allow reception of signals way to
weak to be heard under the noise picked up by other (not resistively
terminated) antenna designs.

Doug Kniffen

"Ditto" on your comments, Doug. The T2FDs I've built have been quiet antennas and revealed signals that were previously covered up. I never tried transmitting with one, though.
In the early 1990s I wrote a T2FD construction article that may be of interest. It appeared in an early edition of the Fine Tuning's "Proceedings" books, but has been posted on the Hard-Core-DX site for years. The URLs to the pages of the article are:
http://www.hard-core-dx.com/nordicdx/antenna/wire/t2fd.html
<http://www.hard-core-dx.com/nordicdx/antenna/wire/t2fd.html>
http://www.hard-core-dx.com/nordicdx/antenna/wire/t2design.html
<http://www.hard-core-dx.com/nordicdx/antenna/wire/t2design.html>
http://www.hard-core-dx.com/nordicdx/antenna/wire/t2fdcomp.html
<http://www.hard-core-dx.com/nordicdx/antenna/wire/t2fdcomp.html>
My best T2FDs were the ones built from VERY sturdy materials and with the wire pulled VERY taut in order keep the antenna as straight as possible without droop (and to maintain the optimum 30 degree tilt angle). This isn't easy to do with a 90mb tropical bands T2FD that's almost 100 feet long!
Guy KE7MAVPuyallup, WA

From: ferrox4
Topic: 8877 Message: 8877

if i were to make a big loop, can i connect it directly to my receiver? where would the positive go and were would the ground go? or would i just use a pick-up coil to magnetically pick up the signal? still even with a p[ick up coild where does the ground go and where does the signal lead go? also when you purchase a wellbrook ala-100 it doesn't come with the actual loop, so what is it that your buying? an amplifier, matching unit? i've never used a loop, always longwires and such, but i would like to try one. thx, john

Not a clue, just did not get out. No contacts were made for that Field Day with that antenna, despite trying for several hours. Not one. However the homebrew Buddipole was great. Since then I designed another Field Day antenna that we now use. We made contacts coast to coast on 20 and 15 meters, and all over the south on 40 meters. This was at 50-100 w.

I've got a B&W T2FD, 90', came from an SK. While seeming 'deaf' the reception did seem to have a lower signal level but better S/N ratio. I didn't try to Tx very much, but the modeling I've seen, possibly Cebik, shows lower gain than a standard dipole. It is not meant as a DX antenna. I think the Navy had it developed to be capable of being used anywhere in the HF spectrum. It is used with the systems that hop frequency, also, just can't remember what that's called. A versatile antenna, maybe, high performance? No.

For amateur or swl use it can be a decent Rx only antenna if it's inconvenient to set up something better.

Hi John,

The Wellbrook site explains what you get with each product. For the
ALA-100(x) you get the amplifier module, DC power injection module with
attached coax to connect to your Rx and wall wart. You must supply the
leadin coax and wire for the actual antenna loop as well as the loop
support structure materials.

thx don!

ok with that said would just building a big loop (i.e. without the ala-100 module) and connecting it to my receiver buy anything? i have the room to go high and fairly wide with a loop. how would something like that connect to a receiver? obviously you wouldn't connect the ground and signal lead from the back of the radio all to the loop?

Don't know what frequencies you are intending to use the loop for but
for SW Rx you'll probably need a un-un/balun at the loop to connect your
coax run into the house. There are "experts" on the list that will
probably explain this in more detail than I can.

don, thx again. i'm actually using the PA0RDT Mini-Whip. I built one and it works great. I have it up about 30ft. Beats my longwire especially on LW and MW. Works great on HF also. How does it compare to your ala-100L?

Thanks again, john

Hi John,

Well, the PA0RDT is more immune to lightning type noise. The output is much lower than the my ALA-100L's as they are so big, 15ft x 30ft. But it is nice on an occasion to have a omnidirectional antenna. My space is restricted here so active antennas are the way to go for me. The first month I had a PA0RDT I logged 62 new NDB's and then took down my random wire antennas. I'm lucky to be able to orient my ALA's almost E/W and N/S.

8885. Wellbrook ala-1530 question

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-02-04 01:10:24 UTC
From: J Ferrow
Topic: 8885 Message: 8885

Hi, I recently picked up a Wellbrook ALA-1530 amplifier unit. The person that sold it to me did not have the actual loop section, said he lost it in a storage unit. I got a good deal on it so I bought it.

I've never seen the loop section in person and was wondering if I could just make a loop out of copper tubing or such in the same dimemsions as the oiginal. would this work?

I would appreciate if an owner of an ala-1530 loop could let me know exactly what the loop consists of and how it connects to the amplifier section.

Thx again, john

What you may have is just the DC power injection module. The actual amplifier has the metal loop permanently attached to it - it is inseparable. Take a look at the Wellbrook web site.

Hi John,
Is this a later 1530 model, not the latest version? Did you get the 12 volt regulated wallwart and the power injector box to go with it?
The original loop on all of these is a 3/4" diameter hollow aluminum tube of a little less than one-meter diameter. Both ends just insert into the plastic housing and are held in place with the sheet metal screw through the housing. Hopefully your preamp box has intact connections to the interior of the preamp otherwise you're in trouble.
But you can make a considerably more sensitive loop system by using a larger loop, since you don't have the original stock loop. I'd go with something like a 4-6 foot diameter loop. Any type of copper or aluminum tubing would work fine, and in a pinch a larger diameter coax cable such as RG=8 could be used, with the outer shield being used as the "loop" conductor. Of course using coax cable, you'd need to rig your own support. But rigid CATV tubing could also be used, if you have access to that..
And should you not have the mating power injector box or 12 volt regulated wallwart you can make your own injector box, and use a standard linear 13.8 volt supply. However you need to use some rectifier diodes in series as all the Wellbrook loopamps are designed to run on 12.0 volts, not 13.8 volts and will overheat and possibly burn up if run directly on 13.8 volts.

Steve, Thanks for getting back. The box i purchased says antenna interface with an antenna input on one end and a receiver input on the other end. I also have the wall wart. I don't think this is a newer version, but an older version. I'm guessing that what i purchased is the power injector box? i didn't spend a ton on it and in fact after lookjng at the pictures of the ala-100 i'm getting a sense of how this all connects. looks like i'm missing the most important part the actual antenna electronics. oh well.

Easy enough to make yourself with 1/4" plywood, 1"-2" diameter wooden dowel and some wire
,,,,

Cut six 4" pieces of dowel and two 1'x2' pieces of plywood, separate the pieces of plywood with the dowels, one in each corner and one on each of the long side at the mid point

Wind 12-13 turns of wire with about a 1/4" spacing

Put it inside a cardboard box so no one can see all your Wave Magnet consists of nothing more than a small multi-turn untuned loop

A 'Down and Dirty' one can be made on a 12"x24"x4" (give or take) cardboard box with a little packing tape holding down the wires

Seems to work best with the old All American 5 type setup with a variable tuned input filter on the front end and not so well on modern wideband/fixed tuned input filter up conversion style receivers

Hi all, I just got finished building a mini whip e-field antenna that is nothing short of amazing. it rivals the LFengineering skymatch antenna and cost me alot less. I'm on a roll now and was wondering if anyone had any schematics or has built a broad band active magnetic loop similiar in performance to the wellbrook ala-100. would love to hear from people who have homebrewed one successfully.

sincerely, John ki4ucw

You'll find the design for a wideband loop antenna amplifier that outperforms both Wellbrook and Pixel here:

You can learn a lot from one of the free antenna modeling programs
like 4nec2 or maybe mmana (sp?) Takes a while to see how to work it,
but it can be very useful.

I'm getting ready to put my Kiwa Loop up for sale on ebay next week, just wanted to give folks here first shot at it. It's in good cosmetic and working order but is being sold as is. These have been going for about $550 to $600 on ebay, I'm asking $425 plus shipping. Any takers just send me an email.

I was thinking of a title I hope this one will do.
I am thinking of making a spider MW BCB loop say about 24 x 24 inches in one corner it will have a tin foil slider tuner, in other words a post card with tin foil one side and a stiff slotted envelope the other, you slide in and out to tune the loop, you mark on the blank side the frequencie, thing is can anyone workout what pH the tuning slider would be, what lenght the tin foul should be and so on, I am thinking for the coil to use alarm foil or sticky copper strip if
i can find same, this to go as
i said on a bit of large card maybe even making it so that it folds we shall see and I await your input. Mike UK.

Mike,

I was tinkering with a crystal set one day a few years ago to see what it could tolerate receiving in town, early on had a 30 ft aerial pointed NE would pickup locals and at night on a good night would get WWL in New Orleans, 280 mi south. I even tried it with a 50 ft coil of 8" diameter that I used to boost a signal from Nashville, TN to listen to WSN (?) Grand Ole Opry about 400 mi NE of here. It's signal was weak locally as expected.

After using a tapped coil, I changed to several V-caps and then with two pieces of aluminum foil about 12" square and waxed paper for the dielectric that tuned as good as the other tuners. I didn't mark the frequencies, deciding to change the 1N34A to some other transistors, LEDs that didn't work but found a rusty nail and sharp pin to find a hot spot if I had the right spot and pressure. A corroded penny also worked but crudely. I had started to anneal a stainless steel razor blade to use with a pencil lead for the detector but diverted to another subject of one-turn loops in my office when the aerial went down.

The size and shape of the foil might be dependent on the length of the coil wiring, not well versed in that sort of thing nor can I tell the mF of my V-caps just by looking at them, if someone has a good guide on that. I hadn't considered a circular tuner with foil until visiting this site,

It's a long 50 year story of SW listening with my Tech license being issued 2 years ago and general 1 year ago, really slow learning how to use this new fangled Kenwood TS 2000, still studying antennas and for many years and just now putting a home made dipole on my wood fence as a start in HF until I can find a safe place to install it higher.

I love the idea of Tx loops but will have to wait on them for now. If MFJ can make them, so can I do the same.

Hi Bill,

I had a xtal set in G'ville years ago I thought was pretty hot. Had
two coils and a dual gang variable
cap, so wouldn't have worked with a tin foil cap. I could pick up
WWL every night after the locals
signed off, but don't remember picking up WSN or anything except WWL.
Antenna was a wire in
the attic, probably the entire length of the house.

My wife passed away Jan 30, after a 3 month fight with lung cancer,
and I'm still very tired all the time.
I'm pretty much unemployed, only work when they need me. They need
me at the moment, so get
some hours, but pretty much the last few weeks have been spent
dealing with banks, insurance co's,
etc, and cleaning the house, discarding her clothes etc.

John,
I am truly sorry about your wife's death. Please give my condolences to your sister. I saw her photos in the GHS reunion, didn't recognze her.

I'm 67 with MS and SCD plus herniated discs that hurt my back standing or walking, limits me everywhere. I don't mind dying, just don't want to suffer. Our class of about 35 is already planning our 50th class reunion and 5 have died already, one in superb shape died suddenly with a blood clot and the others lingered a long time, pitiful shit.

I made all medical decisions for my parents during Alzheimer's destruction, also after they died, buried their ashes and I had to start taking tranquilizers and anti-anxiety drugs just to tolerate their declining health, broken hips to coma and finally starving to death. I haven't finished dad's estate after 2 years due to some stock that is drawing good interest/dividends and some land from my mother's home that belongs to us 3 kids.

The 8" loop was used with my various AM receivers, not crystal set, to get WSM Nashville clearer and found out that some of the cheapest radios would work better than my RS Dx 398. I was told add a resistor in parallel to the sterio plug to make the 398 accept the loops, not the aerial, not sure how to do that but apparently it shut down the internal antenna. What do you know about that?

My crystal set was just wired up with farhnstock clamps and alligator clips so that I could wire in a new component at will. Without the coil and V-cap, no tuning, it would pick up <6 MHz Christian stations, Radio Havana at 6.0 MHz and others loudly and I didn't know the frequencies until they announced it or I hunted and verified with the 398. 30 feet aerial was somewhere close to quarter wave, 41 feet would be best for 6 MHz but at that time I had no idea of antenna designs for reception and the wire was from my office window to my small shop. I studied the calculations for the basics and still studying the esoterica of antennas.

thank You Bill for your imput I am mainly thinking BCB MW loop I should have been more clear on that my fault, I am now thinking to have it fold like a checker board with the wire under a sheet of cardboard for protection, the slide tuner will be in one corner it should work after all during WW2 the POW guys used I understand cig paper and cardboard for there hidden radios tuning system, but as I said it will be a Medium Wave loop, used by inductance. Mike - England.

Hi. There is no ground to a loop, its a loop, hard to explain but think of a O with a break gap at the bottom if you have a old tube radio there will be two antenna holds each open side goes in one hole same if you have a tranny the 3.5 jack lead or the 1/4 inch jack takes the two wires long pin and outer case into your radio, not much more to say apart you turn he loop in the direction of the wanted station, you can put a over wire in the middle of the loops turns to your radio input or just put the radio inside the loop or have it side ways on. hope this helps. Mike - England.

Hi Dean. Those links were very useful, I will make the first one the round turnable cap and the bolt slider looks good as well, I can now see that my envelope idea might very well work, it may need to be about 8-12 inches long, I am ging to use some cardboard covers one side tin foil the other side plain that can be got from a takeaway, anyway thank you very much for the links, 375pf is a good start useing ther circleuar idea, 500pf have been better, I will report back later with my findings as to if it tuned from 1.602-530 khz MW BCB. Mike - England.

Topic: 8912 Message: 8912

At my present location I have absolutely no way to install an outdoor antenna. I am encouraged after monitoring this group for months now that a well designed indoor loop might work for me. My receiver is a Ten Tec RX3230D working into a gateway E2500S desktop computer. The receiver and the computer are close together on my radio table. Our central heat and AC system is noisy. I do have, however a large walk-in closet located 15 to 20 feet from the receiver and computer, and there is already a run of coax(originally installed for cable TV but "rung out" by me as continuos) from just below my radio receiver table to the far wall of the closet. I believe I could install a shielded loop about five feet above the floor, and it could rotate 360 degrees without obstruction. There is no convenient AC outlet inside this closet so power for any loop electronics would have to travel down the coax to the loop or be located at the receiver end of the coax. This is what I have to work with. Can I use an available commercial shielded loop in the above described environment? I have been using a homebrew 30 inch active whip and a homebrew 20 turn 3 foot by 5 foot active loop. Each works, but noise is an ongoing problem. I want to try a rotatable, shielded loop. Thanks for any constructive input. Bill Young WD5HOH

8914. Beginner question - Varactor tuning diodes references

GE All,

I know it's a possibility that this question or a similar one has been ask many times...

I found I could try varactor-tuning for one of my new RX antennas. It's a coper tube square loop antenna, built wih 18mm diameter tube. It's 250cm on each side, for a total lenght of 10m.

It's primarily designed for 160m RXing, in parallel with a 35-950pF variable capacitor. It should tune with 720pF. A High Z in / Low Z out switchable preamp is in construction.

But I want to try varicap diode tuning. Here is my question:

What are the characteristics that make varicap diode suitable for RF Design ? How do I know it's suitable to a particular frequency range ?

Are there "standard" varactor diodes references that are latgely used by varactor-tuned loops builders ?

Tom,
Tell us how it is working for distance and if you have the stepped remote motor installed. How far away are you to the antenna when transmitting?
Will you use it in your attic?
I liked that design if the cap is available anywhere or a substitute is available. I'm a new ham at age 67, retired 20 yrs and able to buy what I need but rather make my own. My radio is the Kenwood TS 2000 and I hope to use its 100 watts for everything, no amps or tall antennas here. I have a power line, 220 volts overhead but I'm stringing a homemade dipole on my 5 ft tall wooden fence with coax under the power line for my first HF antenna. I can change the orientation 90 degrees if necessary due to noise.

All said, there is one practical difficulty in trying varicaps for Rx loops.
Due to height of antenna that is needed, the lightening related voltage surges might damage the varicaps.

Mvs,
So, how would one be protected? I have a dual band antenna, MFJ-1522 for 2M/70cm that is not grounded by itself and just to make sure each day, I disconnect the antenna and power cord to the power supply.

I've been working on a ten foot loop for AM. It has to go outdoors due to its large size, which mean I absolutely have to use varactor tuning.

I've tested the varactor tuning system, and all seems good. The same performance I get out of a tuning capacitor.

I'm using NTE618's. Mouser has a lot of them still, but they seem to be rapidly going obsolete, so get them while you can. They are the only part number I've found with the necessary capacitance ratio for AM loops.

I've based my design on the input stage of a GE Superadio 3. Not many nodes to the circuit, so I'll just give a text description.

Indoor remote tuning board:

Two 9V batteries in series, across a 20 turn pot (single turn could be substituted). Tuning voltage comes off the variable terminal of the pot. I could get more resolution by making part of the resistance range with a fixed resistor, probably a good idea if you are using a single turn pot. You only need about 10V full scale, and you could fine tune further by eliminating about 1.4V on the low end.

At the remote loop:

Ground: tuning voltage negative, anode of varactor, one side of 0.1uF ceramic capacitor.

(node 1): Cathode of varactor, one side of loop.

(node 2): Other side of loop, other side of 0.1uF ceramic capacitor, and one side of 1Meg resistor

Tuning voltage positive: other side of 1 Meg resistor.

Of course you need a four wire cable going outdoors to the loop, because you need two connections for the sense winding. You could combine one side of the sense winding, I guess, with tuning voltage ground.

I did find that the tuning voltage is extremely sensitive to noise on the power supply, which is why I used batteries.

And this tunes a loop originally designed for a tuning capacitor very well. And remotely, which is awesomely useful.

Tom, Thanks. I have an attic, but I'm still working out whether or not I actually have an unused run of coax from my radio operating position through a junction box in a closet all the way to the attic without interrupting my AT&T high speed internet service. I think I have figured out what to measure and how to measure, but I'm still working on it. Also, I no longer transmit. I have the luxury of optimizing any antenna system I build for receiving only. I want to receive essentially as low as possible(down to 10kHz?) to 30 mHz. So I prefer an untuned, broadband loop. I want the loop to be 365 degrees rotatable from a fixed position, and I may be able to locate it in my attic. If it's located there I will hope I can rotate it for minimum man-made noise and leave it in that position. That remains to be seen. If the loop cannot be located in our attic I will locate it in the large closet. I would have better access to it there, but it would be closer to ground. In addition I would like to include an ANC-4 Antenna Noise Canceller & Diversity Combiner (or the MFJ-1026 Noise Cancelling Signal Enhancer) in my receiving system. I think I could use my existing active whip antenna as a "noise antenna". That's an outline of what I have in mind. I'm probably looking at $600 US minimum to implement this system, so I will probably think about it and discuss it before buying anything. I am open to any relevant experience, opinions or data. Bill

To the best of my knollage I have never seen a wide band loop, loops have a very narrow or Q tuning position and this is why they can compete with yargis and are better noise cancellers.

I have tried other Noise Cancelling Signal Enhancer and sold them all.

My loop can tune from 80m to 17m.

Use a wire or wide band antenna to find the signal and then change to the loop.

One other thing, have you tried CQ100. It might not be real radio but when you are in my position or in my environment it's great

Tom

I could get more resolution by making part of the resistance range with a fixed resistor, probably a good idea if you are using a single turn pot. You only need about 10V full scale, and you could fine tune further by eliminating about 1.4V on the low end.

Sounds like my kind of circuit, couple of points I`m not to sure of
though...

1/ Two 9V batteries in series, ACROSS (??) a 20 turn pot.

2/ > Of course you need a four wire cable going outdoors to the loop, because you need two connections for the sense winding. You could combine one side of the sense winding, I guess, with tuning voltage ground.

Could you draw a curcuit layout please??

Thanks.

there are other devices like SANYO SVC388 and 389(SOT23) - both dual varicap for am band.
secondly Toshiba has 1SV149. ASIAN SOURCES HAVE LOTS OF THEM
svc still sold by RScomponents of uk

9V + 9V = 18V. A lot easier than putting a bunch of AA's in series to make 10.5. The varactor needs about 1.5 to 9.5 to tune the AM band.

> Could you draw a curcuit layout please??

Eventually. I suck at ASCII schematics - which suck anyway. Draw it yourself from the node I described, there are only 4 connections in the whole schematic.

perhaps we can have one single 1.5 V AAA or even smaller cell in series to 9V battery meakes aan economical proposal.

Just look at this article, with proper schematic and explanations and all.
He uses a 9V battery. Same thing, add your 4-line cable if you want it to
be really remote.

Here is a complete construction article with schematics
and PC boards available:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

BTW, you don't need sense wiring because the current is
essentially zero and you can send the tuning voltage over
the feedline, as described in the link above.

Mvs,
This is getting too complicated for me to understand. Is this about verator tuning for loops, a complete system, new and still available? I can't find any prices for them.

Thankyou for the url Rick...very interesting reading.

As I have an ant(untuned inverted L) which is adequate for AM using a 9:1 transformer for impedance matching...I am looking more for 17m to 6m and general coverage shortwavebands and am using a homebrew magloop with air spaced variable cap electro-mechanically tuned...(would love a vacuum cap but can`t afford one) but do like the varicap methods described in this thread and your url looks the best start to experimenting, the varicaps mentioned are for 50khz - 200khz...which ones would be suitable for 17 - 6 metres??, never had dealings with varicaps ... lol. I thought they were capacitance rather than frequency operated, shows how much I know.

Regards.

Lee...G6ZSG.

Steve,
Do I assume correctly this loop is not for transmit? If for Tx, do you have a close up photo of the tuning circuit?

These are just receiving loops, using varactors for remote tuning. I had thought you said you just wanted an indoor receiving antenna. They are all homebrew, nothing commercial like these are offered.

The NTE618 varactor is specifically for the AM BCB 500 kHz to 1700
kHz. For shortwave, you need much less capacitance, and lots
of diodes are available in those lower values. There would
be nothing in principle to prevent you from scaling the
loop design in the NCJ article to higher frequencies. Varactors

have a capacitance inversely proportional to the bias voltage raised to a power between .5 and 2. Why would you want a vacuum variable capacitor in a receiving loop?

I think that sentense with a "," there ....9V batteries in series, across a 20 turn pot......was perfectly alright. it clearly sounds that 18V would be across the potentiometer.

I dont know why any confusion!!

Heh heh...it may sound right to you, but not to me!! :) lol.

The batteries in series sounds ok but 18 volts ACROSS the pot ...
think about it..maybe I`m wrong, at my age I wouldn`t be suprised.

Anyways...I have followed your directions and put them to paper
(not too difficult after kickstarting my brain) and made a cicuit
board, using a hobby knife on a copper clad board and soldered the
main components in place but in the absence of a varactor am using
(read :- experimenting) leds and diodes out of my junk box...and
getting some results with leds, not sure what but varying the pot
alters the `S` readings...

Hope you see the funny side of my assertions :)

Regards.

Lee...G6ZSG.

8939. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-01 13:24:43 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 8939

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#2. * Torus Tuner 27" Loop Antenna (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Hi Rick.

Been searching the web and found about 8 suitable varactors that
would do the job including the NTE618, but have a local ham rally
where a local mail order business has a stock of BB112 9volt diodes
will be attending, so I can collect quicker than delivery..and browse
various stalls at the same time, nice day out.
Why would I want vacuum cap? because my 3 foot dia magloop is for tx
and only covers 28Mhz to 16Mhz...

Regards.

Lee...G6ZSG.

8944. Wellbook ALA100

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-03 08:28:28 UTC
From: stephen_qrp
Topic: 8944 Message: 8944

Hello

I have just completed constructing a 12ft square loop with 2 turns of wire connected in parallel at the Wellbrook ALA100 feed-point.

I cannot decide if I should mount the loop horizontally or vertically.
The loop will not be on a rotator and so I will not be looking to "null" at all. My feeling is to go for horizontal, but would welcome any suggestions.

Another question I have been pondering, is the location of the feed-point. I read a technical paper on loops that suggested that the location of the feed-point would influence the polarization of the loop. Unfortunately I am not cleaver enough to understand the why this might be the case.

Regards to all.

Stephen

Stephen,

The loop dimensions you have given are more suited to the ALA100M. If you are using the ALA100 or the new ALA100LN (low noise 8 JFET version) then a much larger loop is required. You can use any loop mounted horizontally. However, the gain drops off significantly where the ground to loop space difference is less than say Lambda/8. Or put it another its is more suitable for HF.
Where the loop circumference is small in terms of wavelength less that approx. 0.2 Lambda, the antenna polarization is function of its physical mounting and not the feed point. With large loops, for example a full wave, the polarisation is dependant on the feed point. With a vertical mounted loop fed from the bottom, it is Horizontally polarized and Vertical polarized if fed from centre of the one side.

Kind regards

Andrew Ikin

andy good info - i have an ala-100ln on the way - i have questions about loop size also.

what is the smallest loop size i cold get away with using with this amp? based on your response it sounds like its not even practical to use the 100LN with a rotor. finally what would happen if i did use the 100LN with a 12ft loop as suggested by the original poster.

thx, john

Hello Andy

Many thanks for your kind reply, I should have been more careful in stating that I have the ALA100M.

As I understand your answer, should I want the 40m meter band then 40/8 is the minimum height above ground for a loop physically mounted horizontally.

However if I mount my small loop physically vertically then height above ground is less of an issue and can be fed from the bottom..

My understanding is that a vertical loop is more directional whereas mounting horizontally it is more omni-directional. My thinking is to go horizontally mounted at about 18ft above ground for frequencies of 8 MHz - 16 MHZ unless you say otherwise.

I use your 1530 and 1010 for other frequencies and have noted that mounting them horizontally is definitely not a good idea.

Kind regards

Stephen

I use your 1530 and 1010 for other frequencies and have noted that mounting them horizontally is definitely not a good idea.

Kind regards"

Stephen what you say is more or less correct. However, at HF where the signal arrival angles are higher or where the same signal has multiple arrival angles, a vertical mounted loop will appear to be omni-directional. Mounting the loop horizontally may reduce some very high angle signals.
Kind regards

Andrew

John Ferrow, wrote on March 3rd,

"andy good info - i have an ala-100ln on the way - i have questions about loop size also.

what is the smallest loop size i cold get away with using with this amp? based on your response it sounds like its not even practical to use the 100LN with a rotor. finally what would happen if i did use the 100LN with a 12ft loop as suggested by the original poster."

John, You can make the loop smaller, by using 2 turn loop, but you need to space turns by approx. 3-4 inches to keep the loop inductance down.

Kind regards

Andrew

Heloo
This message is off topic but I don´t have somewhere to wrote else ...

It is now 2 weeks since I a huge noise has been introduced to my already heavy QRM ed home from DSL at least.
MY system consists of a R75, a 2x16 inv V antenna a 16 H antenna
This noise adds a S10 level QRN on most bands ie wiping most radio stations and is cut on 7 MHz and above 15 MHZ

You can find a sample on this link

http://soundcloud.com/greekdx/qrn-1

Just a little research with my `field meter´ Jupiteru 7100 finds the source as the electric panel from an Italian pellet burner on the cellar of our house
Look at the 18secs video :
http://youtu.be/FUxBUo7kTJg

with attenuated signal level
Do you have any idea on how to kill this noise? (esp from the burner side)
Standard rig : ICOM R75 / 2x16 V / m@h40 heads Sennheiser
Please read and distribute this 15 year research article http://tinyurl.com/5vzg7e
Please read my article on SINPO at http://tinyurl.com/yt7qjd

Hard to say without a schematic diagram or understanding of the theory of operation. First thing that comes to mind is it looks like there are no electrical filters on the power lines. Poor shielding on the assemblies, or insufficient electrical grounding (earthing).

Many power adopters(wall bricks,though analog) are not designed well to suite for radio working. they needd to have 0.01uF ceramic disc capacitorss across the diode elements. liewise they need to have a sort of linear regulatorwith proper filtering.

secondly, many desktop psus are bilut and sold with no front end emi filters even though they have provision on the printed board inside. I tappears that we have to place a filter as it could be mounted replacing the 3 pin sockt of the psu.

perhaps we need to prevent RG cable parallel to either internet (DSL cable, or some such. the leadin should not be parallel to a power duct.

during the active Dxing times we can swith off the chopper type fam speed regulators etc to prevent interference.

Once we start examining and eliminating, we find slow improvement.

From: jacob
Topic: 8954 Message: 8954

Hi Group;

I just found the group and I'm excited to see what others are doing. I have been experimenting with mag loops for about 2 years now. I have two that I use very often. One is transmitting; a five foot diameter 5/8in flex copper affair with a vac. variable - tunes 60 meter band to 17 meter band and works great! My newest is for the AM broadcast band and uses about 5 turns of small wire on a 3 foot frame. It all came from my "junk box" which I think is cool.
I am very interested in taking the mag loops to the next level which for me will involve making them more aesthetic (better wood or the big guy)and setting up a remote tuning control.

On a separate note: I have found that several friends, who otherwise have minimal interest in radio, are absolutely fascinated when I pull out the loops! There is something really unique in hearing the noise peak, the signals appear, and then turning the loop to really "lock-on" to the signals. These things are just neat.

73;
Jacob K4JQV

Hi Jacob,

I also share your facination with loop antennas having used and built several.

My current project is building a BCB receiving loop from a 23" diam quilting hoop, 12 turns of #28 wire and a 365pf tuning capacitor, to use with my portable AM radios fo BCB DXing.

I've also built and currently use a dual band receiving loop for 160M & 80M which works great for removing atmospheric and lowering local noise levels.

All the designs I've found on the web.

When I got my General Ticket back in 2001, a friend loaned me his MFJ tuned loop to use until I could build something else. It was fun to have, but required constant re-tuning after moving the VFO on my rig. I quickly moved over to a random longwire antenna which I still use to this day, as it's quite stealthy and, in my neighborhood, that's a necessity.

Welcome to the group!

Bill - WF1L

I would think that it should be a market, for home made AM LOOPS?
How should it be done, individual or through a store front?
I think this would bring in extra income for builders and help MRL/SWL?

It is a rather esoteric hobby, I'd think you would have to be in a very big city like Seattle to be able to afford a storefront.

Etsy seems like it might be a good place to sell AM loop antennas. I've been thinking about it myself.

8960. Making and Selling MW BCB loops

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-10 09:39:45 UTC
From: mike.evans191
Topic: 8960 Message: 8960

Hi from across the pond {England} some years ago I did make and sell a 40 x 40 loop getting it in the post was a problem but it did go parcel post, getting a box carton was a bit of a problem but super markets helped.
It was a double H type made of 1 x 1 inch pine wood, turn one H on its side a slot the two together and your get in idea, some would call it a spider web loop now get the idea, anyway it slotted together to form that 2 x H and the holes for the wire were on each end of the loop 8 ends with 7-9 holes which I pre drilled making sure there were all in line, winding and pulling the wire all of about 90 feet or more into each hole and going around and around took some time and space with manny a time getting in a right tangle, someone side why not slots and slip the wire in! I tried this but the wood broke at the hole points I even used choc block but you still had to put the wire in those holes.
To stop the wire pulling and bending the frame I put bits of wooded strip across the top s of the H eg 4 bits.
The tuning cap was on a flat bit of 8 x 4 plywood {Note the gap of each top of the H is 7 inches} at the bottom a shelf was made to hold it the tuning cap at the back.
I used full sizer slow tune 500pf tuning caps these were not cheap even from ebay, in all I made about 25 loops each one costing just £40 with £10 postage was I crazy to charge such a low price after all my work, maybe but when I ask for £60 via a UK radio mag no one came forward.
I next tired selling them in do it yourself form, most buyers ran into problems evan glueing the two H bits together in the end I gave up on them.
Would I restart making them NEVER. Sorry on picture to show.
One other idea is to use large underground black or orange pipe some can be as big as 24 inches across just cut a 2 inch wide bit, some even has a grove on the outside to hold the turns, so there you have it, you can sell your home made loops but the hassle, would it be worth it. Michael - England.

The Ultralight DX group on Yahoo

http://groups.yahoo.com/group/ultralightdx/

has many recent messages about Ferrite Sleeve Loop antennas (FSL) for the MW BCB which use a number of ferrite rods wound with Litz wire and a variable capacitor, to get the equivalent performance of an air loop many times bigger. As well they have info about making air loops. Worth checking out!

Yes I was a member and left the group I could not find one member who was selling what he had made and there was so many boring pages about ferrite made loops one week in was 6 inch the next 9 then 12 then back to 6 it just went on and on give me a real good size loop anyday, by the way the ferrite loops were so heavy that the loop was bigger than the radio and twice as heavy. Michael Uk.

Tell me what you can offer me and its $price shipped to zip 75949, if you had rather sell it on Ebay to a highest bider, then I will bid on it. Just tell me, what to look for?(LW, MW, SW)

It's pretty easy and cheap to make one, you can find instructions by googling and it can be a fun project costing less than $10-20 or so. The loop can be designed for different ranges of frequencies.

If instead you want to buy one, for MW BCB at least you can find various on eBay looking for "loop antenna", here are several. I can testify that the Terk Advantage is effective and fairly small, I think it's a good value overall. I did not check for price variation so you may want to look around to find the cheapest seller:

From: mike.evans191
Topic: 8966 Message: 8966

How would I start making a BCB loop if I did not know how { I do know{ for the first timer your need WOOD - WIRE and a veriable tuning condenser that vain thing thats in a old time radio, plus some GLUE.
You could go on YOU TUBEwhere guys will show you how to put such a loop together, but they will not tell you the cost here I will, the tuning veriable will be found either as I said from a old rtube radio or on ebay, on ebay the price for a 365 or a 500pf will not be cheap because there getting rare, the wood should be about $10 I am trying to think in US money your need to have it cut to size and countersunk groved more on this later, depending on the loops size, but lets start with a 40 inch loop my favourite, useing 1 x 1 inch pine with pref no knots in it have the woodman counter sink the wood so that it forms a H frame it will have a square of 9 inches in the middle press in the counter sunks together to form the frame BUT not before you drill on each courner of the up rights re H top and bottom of and the H layed on its side so they cross each other, after this has been done then put the glue in the counter sunk groves and clamp down, you now have the main frame are the holes all in line I hope so. With about 120-130 feet of wire it can be almost any type passed the wire into the bottom hole of the H pref the right hand side and pull the wire to the next hole and the next until you go all around till the bottom of the H and the bottom left hand side hole go up a hole on the right hand side of the H and keep on go around untill you have filled all 9 holes, these holes I should have side should be a 1/4 inch apart, time to have a rest and it is hope you did not use a few bad words with the wire pulling, with the two ends of the wire now at the bottom of the H cut off 12 inches of wire, you should have 2 x 12 inch tails, solder on one end to the main metal side of the tuning cap the other end to the tag your see in the middle the loop is now made, place a radio close by find a weak station a turn the tune knob on the variable the station should now be pulled in. NEXT TIME THE OVER LAY WIRE called the INDUCTOR. hope this was helpfull, any problems just post. Mike - ENGLAND

8967. Pixel PRO-1A

Yahoo group: loopantennas (2008 — 2012)

From: slsfron
Topic: 8967 Message: 8967

I have a PRO-1A and I thought worked pretty well. Recently I purchased the Clifton Labs Z1501D Active Antenna and it receives hands down uch better then the PRO-1A. The Z1501D is mounted on a pole about 7' high, and the Pro-1A is mounted on a 14' section of Rohn 25 with a 5' mast. Of course the Pro-1A has a rotor to turn it. Both are fed with premium quad shield coax which is mostly buried until it goes up into the attic to the radios. I wonder if the Pro-1A can be upgraded to the B model and if that would make a difference. I am basing my experiance with both antennas while DXing NDBs.

Ron,

Recently, I contacted Doug Talley at Pixel re the same question, as my Pro-1A was bought directly from them a year ago. I sent him pictures of my fixed loop installation. He said my amp was okay, but the new and improved 'B' loop would be an improvement and he could send me one for $200. I didn't take him up on his offer. I may call him one day and find out just what improvement I could expect. The antenna was $350 - the loop shouldn't represent over half of it's cost - and it makes me think they shipped me 'old stock' when I bought my loop - not a great feeling since the 'B' was out just days/weeks later. Maybe I just feel a bit burned. The loop did null EMI from arcing high tension insulators in front of my house, but that changed in January when a tornado came through my neighborhood, taking down many such power lines. Listening now is very sporadic. I was impressed with the loop.

Hi Ron,

Just received my PRO-1B at some expense in Australia. So far impressed had WWVB 60khz very strong this morning,using either my Watkins Johnson 8718A or the JRC-NRD545DSP I don't have much to compare it with but works well as far as I can determine.Oh yes this is indoors at ground level of a villa.

What have you noticed about the Clifton in comparison to the loop ?

Most of the time the Clifton Labs 1500D receives NDBs much better. It was pointed out to me that "A good active whip will always be more sensitive than the small loop at LF--that's just the physics of the loop in operation. The loop steadily loses sensitivity as frequency decreases. And an approx. 1 meter diameter untuned active loop is just not very sensitive at LF compared to a good active whip". A larger loop would work better at LF. There is no electrical or performance difference between the upgraded B version and the original A. This is my findings and information from Jack Clifton and Steve AA7U. Both very knowlegable on both antennas. I haven't spent much time on the higher bands comparing the antennas.

Well, had a nice day out and came home with a pair of varactors and a nice clean Yaesu FT 790R 2 metre a multimode electric handbag that after a bit of furtling works extremely well (Kerching)...thankyou.

Had a look at these varactors (36z-w80) which I had been assured runs up to 540Khz at 9 volts.. and set about sorting out the bits and pieces from my junk box to build the Trask indoor loop antenna as was posted earlier in this thread and laid out except for building the loop for 28Mhz to 10Mhz at 10 feet circumference...but could not get it to work!!

Finally discovered it works from 9Khz (lowest freq on my Winradio G305i SDR) to around 1700Khz ...RESULT YAY... verified it was tuning by shorting across the loop input...

Problem - I want to work around the HF bands and am not sure how to convert to the HF broadcast bands I need.. Can any kind person advise please..

Thanks.

Lee...G6ZSG.

Lee,
Re the Winradio G305i SDR, I understand it tunes to 1800 mHz or higher and the quote was 1700 kHz. Was that in error? The kit comes with a short antenna, wire, not loop? What am I missing with this plug-in card for a laptop?

I do not understand the varactor tuning necessary because I'm weak on electronics for loops. My simple inside office wall loops plug into my receiver with an outside ground and work well enough to satisfy me on SW, no BCB. My Kenwood 2000 and a half wave dipole has super receiving (compared to my Radio Shack DX 398) but weak transmitting ability, something I'll work on later.

Hi Bill .. No, 1700Khz was not in error and yes, the 305i tunes to around 1800Mhz...9Khz to 1700Khz was the apparent bandwidth of the antenna that I have just built, also, the 305i does not plug into a laptop,,it plugs into the ide slot of a desktop computor..The whole point?? and IF you DID notice another error..I DID commit a typo...

The radio I bought is a Yaesu FT 290R not a Yaesu FT 790R. the 790R covers 70 centimetres, NOT 2 metres :)

Bill... I am also at a loss when it comes to tuning antennae using varactors but, if you google `magloops` and the way they operate, then maybe you will understand the why and how to tune a loop antenna..

I do hope this has been of use to you Bill... maybe someone more knowledgable than me regarding loop antenna tuning using varactors will be along to advise us both.

Regards.

Lee...G6ZSG.

Thanks, Lee. I am relatively new learning and studying loops for Tx, really need a better antenna than my shoddy dipole.

I looked up your radios on iHam, didn't know they worked on 2M/70cm as well as HF if that is correct what I read. I'm relatively new at Ham radio, everything seems to lead me to a tangent subject and forget where I started with a question.

Again, thanks and I will pursue loops as you suggest.

@bill,
I fear that we should NOT resort to varicap tuning of TX antennae.
the High power coming from PA of the TX rig would just burn off the varicap diode. No lighhtening is need. Let us not waste the costly resource experimenting across the TX antennae.

The concept of use of varicaps for tuning loops is valid only for Rx antennae.

Hi Guys,
My ALA1539 has arrived today and just potting it on a waidow ledge has allowed many sigmals, albeit with lost of noise. I will try and get it outside to-morrow.
However my question is. As I only ever listen to Sw bands and never MW, is there a real need to buy and use a rotator. I believe that short wave signal being 'sky waves' would hit downwards, Therefore there would be no either directional or null obtainable by rotating the loop.
Problem:- Is this right or am I just trying to talk myself out of the need to buy a rotator.
Could anyone out there please advise me at all.
Ron, Aberystwyth, wales,UK

Hello Ron,

A rotator is not normally needed for SW. Try and get the loop well away from the house, this should reduce the noise level.

Loop antennas are directional in line with the plane across the diameter of the loop. You'll need a rotor unless the antenna is low enough to turn by hand.

That is only true for (a) vertically polarized signals that (b) arrive with zero elevation angle. For all other signals, the loop response does not follow the classic "figure 8" pattern.

At shortwave frequencies propagation is by skywave unless you are very close to the transmitter and in general neither (a) nor (b) will be true.

And, the polarization will vary over time as does the angle of arrival.

In these circumstances, a rotor will not be all that useful and isn't necessary.

Since this loop is much smaller than a naturally resonant full size loop antenna, for skywave signals above about 8 MHz, the rotator will generally give you a very minor difference if at all. Below about 8 MHz the directionality will be more observable since the vertically polarized groundwave starts to predominate over the skywave. These guidelines are for farfield signals and vary throughout the day due to ionospheric conditions. If you've got locally generated noise near you, a rotator will help to cancel it out. Unfortunately, most noise sources these days are coming from many directions and you end up chasing your tail. Best thing to do for noise is mount it as high as possible and as far away as you can from a house or powerline.

Hello Ron,
My experience is that I erected an MFJ1788 about 40 feet away from the house and installed a rotor. I use mostly 20 meter as my operating area and the rotating of the loop antenna has no effect on the incoming signal strength or on my transmitted signal. What the rotor does help with is the reduction of noise and for this alone I am glad I installed it. The MFJ1788 is still a pig to tune when trying to respond to a station it simply takes to long to do so. Good luck with your installation.

8987. Buried coax, what effect on a loop if any?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-25 06:29:57 UTC
From: doug12455
Topic: 8987 Message: 8987

I've often wondered if burying the r6 quad shield coax would effect the tuning of the loop. Specifically a Pixel Pro 1B. I know have ground effect with 50' of buried coax for a ground mounted 80-10 HF vertical.

Brian

8988. Burying the coax, does this have an effect on an untuned loop?

The Pro-1B is an un-tuned or "aperiodic" loop.

In general, conductors near a loop can re-radiate signals and distort the null azimuth or in the worst case filling in the null. Burying the feedline a few inches will reduce re-radiation from it and thereby help preserve null depth.

Of course, that won't do anything for other re-radiators. I have a 100 ft tower about 50 or 60 feet from my loops and re-radiation from the tower has a severe effect upon null depth and azimuth above 1 MHz or so.

Brian,

My experience with re-radiation effects, as Jack has described, is similar.

Need more info regarding buried coax effects of your 80 meter loop--what kind of coax are you using?? Are you using a Balun??

Regarding the use of buried quad RG-6 for the pro-1B, I think that it uses a preamp and therefore would expect that it provides some isolation from the loop element and therefore some immunity to imbalance due to coax related effects. The amplified signals from the loop element will be larger and 'overshadow' the now relatively smaller signals that might get picked up on the coax. Moreover, I would expect that high quality quad braid/foil shielding coax, which provides significantly more shielding effectiveness (SE) than a single braid shield, would provide less buried ground effect than your 80 m loop application. Important caveats are that contrary to popular belief, the foil on a coax doesn't start providing significant shielding effectiveness until above 800 to 900 MHz because of the depth of penetration of RF and the thickness of the foil. So for HF and below you're still relying on the braid and the quality, the 'optical coverage' of same. As an example, the quad RG6 I've inspected from Home Depot is poor, having low optical coverage, low number of strands and gaps in the braid. Radio Shack quad RG6 is better, but no cigar. The best stuff is usually used by reputable broadband cable companies or providers such as Belden.

If you decide to use the quad RG-6 for your pro-1b application, I'd be interested in your findings.

Steve:

Have you heard from other builders of the LZ1AQ Loop as to their results ??? You were NOT very happy with your results !!!

I have saved your E-mail (as you can see) for a while- as I have bought the PVC Pipe for the support structure of the "cross-parallel Loop and have it sitting in on my garage floor ready to build it once other projects are done.

Clifton Laboratories has a Amplifier made for Loops that I thought I might buy for about $95. It would save a tremendous amount of time buying the parts and it comes with the circuit board. Not sure if you were aware of this. Believe the Amplifier is based on a Langford or Chris Trask design.

Subject: Re: [loopantennas] Re: Best Bet Loop Type Made with Surplus Cable (LZ1AQ article)

This past summer I did a number of loop and loop preamp experiments,
including building the LZ1AQ loop preamp and the "crossed-parallel" loops in
the mentioned article.
In his preamp I substituted transformers with more inductance to get
response down to LF. But I found the preamp to be noisy over the whole LF-HF
range and inferior to most other loop preamps I was testing. I built four 38
inch
diameter loops and connected them in the "cross-parallel" configuration, and
compared their performance from LF-HF to a single-turn loop of the same
combined area (about 73 inch diameter), with the same conductor width as the
C-P loops. At no frequency did I find the "crossed-parallel" loops with
lower inductance to be superior to the single-turn loop with higher
inductance, no matter which loop preamp was used. My results did not come
close to matching his claimed results. I would
be very interested to hear of other's results should they build the LZ1AQ
loop preamp and/or the "crossed-parallel" loops, and compare them with
single-turn loops, and other loop preamps.
73,
Steve

Hi Garey,
My, that was a blast to the past reading that old email from me of Nov. 2010. I had a lot of fun doing those loop and loopamp experiments.
But no, I have not heard from anyone else who did such tests. LZ1AQ now offers a completely assembled-with-enclosure combined loop and active whipamp module. The loopamp section is probably very similar to his original loop amp that I built and tested.
I was not previously aware of a loopamp offered by Clifton Laboratories but looked it up just now--I assume you're referring to the Z10130A "Fet Buffer Amp for Dr. Dallas Lankford Antennas". From what little I know of such antennas I would say make sure you read that specific article before you assume such an amplifier can be used with other types of loop antennas. I'm not sure that such is the case. I believe the Lankford antenna to be used with this amplifier is a large terminated loop used as part of a multiple loop array. Probably Clifton Laboratories, if you asked, would be able to give more information on the proper use of this amplfier, and if it could be used with other more generic types of loops. But I certainly wouldn't assume that to be the case.
Wellbrook makes a superb standalone loopamp, the ALA 100, which I've used and had very good results with. But that is designed to use a fairly large loop rather than the small one meter diameter loops that LZ1AQ mentions using. I've also used other Clifton Laboratory kits and they all work very well, so I was interested in your comment that a loopamp was now being offered. However as noted above, I would inquire if such a loopamp was suitable to use with generic loops of various sizes and not just for the specific terminated loop mentioned that this loopamp is for.

73,
Steve

Alex,
I installed the Pro-1B today. I ordered the coax with the antenna. Doug states the coax he supplies is high grade quad shielded. I didn't look at who the manufacture is of this coax, but I will. Anyhow I installed it today with a 100' run. Until tomorrow I just have the coax laying across the lawn and up to the house. Before I went any further I wanted to test the loop. So far I'm quite impressed. Has a lower noise floor than my 100' dipole (no surprise). Signal levels below say 3/mhz are higher as well as a lower noise floor (signal to noise). Above that it's a toss-up but the loop always beets the dipole in actual signal to noise.

I may just string it up from the peak of the garage to the house with the proper relief mounts of course.

Topic: 8994 Message: 8994

Hi!

I have kits available for:

3" OD ROTOR + 2 STATOR PLATES $3.50
4" OD ROTOR + 2 STATOR PLATES $5.00
5" OD ROTOR + 2 STATOR PLATES $5.75
6" OD ROTOR + 2 STATOR PLATES $6.75
8" OD ROTOR + 2 STATOR PLATES $9.50

the objective of producing and selling a variety of components and kits for use in the construction and home-brew of Butterfly Type Variable Capacitors,voltage 2.5-15KV
A "Butterfly Capacitor" is a variable capacitor which usually consists of a "cold" rotor plate and two independent stator plates that oppose each other. The rotor plate's shape resembles that of a butterfly, hence the name "Butterfly Capacitor". Butterfly Capacitors are typically used in symmetrical tuned circuits such as RF power amplifier stages in push-pull configuration, antenna tuners and in high current applications as needed in magnetic loop antenna circuits.

These type of capacitors are no longer main stream, nor widely produced any longer, and therefore usually hard to find. When you do find them, they are not cheap.
We are striving to keep costs to a minimum so that the average hobbyist can afford to home-brew RF Amplifiers, Antenna Tuners, Magnetic Loop Antennas and various other RF related items. One way that we are able to make our Butterfly Capacitors affordable is to leave the final assembly for the end user to perform.

We provide the parts that require special equipment to manufacture, such as our CNCr. With our CNC , we are able to produce precision parts, namely the rotor and stator plates. The end user can then stack the plates on some threaded aluminum rod, using pieces of tube or nuts as spacers, thereby saving a large portion of the cost of what a fully assembled unit would be. The items required to finish a capacitor can be found at your local hardware store. We can also supply these items for a slight additional cost.

WE CAN ALSO SUPPLY THESE PARTS FOR ASSEMBLING (,ALUMINUM SPACERS,PLASTIC END PLATES) FOR AN ADDITIONAL COST

If you are unable, or not interested in constructing your own capacitor with the parts we supply and would rather have one delivered in ready to install condition, please contact us for a quote.

Hello Vasile,

This sounds very interesting! I am planning a
medium power AM transmitter that uses tubes, and I'm not sure I will be
able to find the high voltage capacitors for the 813 final amplifier.

Do you have a website showing your kits? Would they need to be shipped from France?

Brian,

Did some tests over the past 3-4 years with a barefoot 6 ft diameter copper pipe loop and also a 50 ft circumference delta loop on a retractable 45 ft tower. Incrementally moving from rooftop level, about 12 ft, to the full 45-50 ft, significantly reduced the unwanted electrical emissions yielding a relatively high S/N and low baseband floor better than about -125 dbm, which was close to the limit of my SDR. These results were repeatable using actual RX's (Collins, Drake, Icom) with their respective lower floors. These results were in a suburban environment, 300 ft from an industrial park and 200 ft from high tension feedlines located at about 60 ft in elevation---a pretty bad electrical environment.

Anyhow I installed it today with a 100' run. Until tomorrow I just have the coax laying across the lawn and up to the house. Before I went any further I wanted to test the loop. So far I'm quite impressed. Has a lower noise floor than my 100' dipole (no surprise). Signal levels below say 3/mhz are higher as well as a lower noise floor (signal to noise). Above that it's a toss-up but the loop always beets the dipole in actual signal to noise.

The amplified signals from the loop element will be larger and 'overshadow' the now relatively smaller signals that might get

picked up on the coax. Moreover, I would expect that high quality quad braid/foil shielding coax, which provides significantly more shielding effectiveness (SE) than a single braid shield, would provide less buried ground effect than your 80 m loop application. Important caveats are that contrary to popular belief, the foil on a coax doesn't start providing significant shielding effectiveness until above 800 to 900 MHz because of the depth of penetration of RF and the thickness of the foil. So for HF and below you're still relying on the braid and the quality, the 'optical coverage' of same. As an example, the quad RG6 I've inspected from Home Depot is poor, having low optical coverage, low number of strands and gaps in the braid. Radio Shack quad RG6 is better, but no cigar. The best stuff is usually used by reputable broadband cable companies or providers such as Belden.

Alex mine is about 12' off the ground. That is about as high as I'll be able to get it in relation to other antennas taking up the needed space. Maybe in the future I may be able to get it in the 35' range. BTW correction on my last post. Beets = beats. I doubt the loop throws vegetables at my dipole :-)

8999. update - a year with the DX Pro-1A

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-27 14:03:59 UTC
From: John
Topic: 8999 Message: 8999

The decision to try the Pro-1A was tough - I'd made remotely tuned loops, wideband loops, active whip antennas, and a myriad of wire antennas over the years. Sadly, the top 30ft of a 65ft pine snapped off 9/2010 and hung precariously ofer both my powerline drop and a neighbor's as well. I had it removed in a few days - while we were on a planned post Labor Day Gulf Coast trip. I came back to find a pile of pine mulching, the only remnant of the huge tree and it's roots. Located 20 ft from my basement den's window, through which all of the wire antenna leads/feedlines were fed, there simply wasn't another choice for a wire antenna support, as the nearest trees were 25ft uphill and behind the house. My antenna had been a 30ft wire run from an eave to the treeline, perpendicular to the house and powerlines across the street. It was matched via a 9:1 UNUN to an RG-58 coax to the listening post. As the hi-Z antenna was so close to the house - and it's wiring - it picked up a good bit of QRM from the various switching supplies and fluorescent lights in the house. The wideband/Faraday shielded loop seemed like a great idea.

I got my Pro-1A quickly - and it was mounted on an old rusty 5ft RS mast section from years back, which in turn was mounted on the skirt of my low deck, putting the loop's bottom at ~6.5ft above the ground. I picked up 100ft of Belden QuadShield RG6, some waterproof connectors, and a 'DataShark' crimper (~$22)from a local TV parts house I first purchased from in 1964 (My Dad had to drive me!). Although it was intended to be temporary, with the loop to be mounted with a rotor ~10ft off the ground and in a clearing in the trees about 90ft behind the house, it's still ~12ft from the house - mounted to the deck.

It's directivity seemed unimportant - with weak nulls - at night on HF. On MF, it did seem to null quite well with ground wave signals. It's main use - to null powerline/house radiated QRM - was unreal - a 3+ S unit reduction in background QRM at HF - a bit more at MF. Sadly, January 27th's F4 tornado cut a path a block above me in the subdivision - lots of since replaced powerlines - and more RFI sources from other directions. Obviously, I can only null such QRM from one line of action. Additionally, the antenna rolls off in response above 22 MHz and below 200 kHz. It could be the antenna or it's power coupling unit. Doug T. of Pixel suggested upgrading to a Pro-1B loop and 12V power coupling unit - for $200. It seems like a lot - especially considering how much I have invested in it now. Oh... the clearing where I was to remount the loop was littered with fallen tree limbs & parts - the loop would have been ruined had it been there! It looks a bit odd on the deck... even drew a question from a contractor, "What's that... some kind of short wave ham radio thing?". The antenna did help in the one way it was hoped to - I can listen to the ever-decreasing number of SWBC stations again. It also had me add an older Icom R75 alongside the Palstar R30A. Perhaps I will DX again!

BTW, with the near 100% shielding of decent, like Belden Quad Shield, RG6, it can be run anywhere without fear of picking up more QRM. If I were to bury my feedline, I'd run it inside a cheap garden hose first - then bury it - for mechanical protection from abrasion and little teeth.

I guess I missed buying a Pro-1B by days - my greatest regret.

John

Burying your coaxial cable can reduce local QRN quite a bit depending on just how bad the local noise is. I live in a typical suburban environment. When I bought my house in 2005 the local noise environment on 160 meters was surprisingly low but with time the noise crept up to an intolerable level.

That led me to build an outdoor rotatable ground level receive loop http://www.wcflunatall.com/nz4o14.htm which was fed with RG-8X coax. The noise on the receive loop was dramatically lower but there still was some. I then buried the coaxial cable and that got rid of almost all of the noise. At a later date I added coaxial choke BALUN's at the antenna feedpoint and radio shack entrance panel and that got rid of the rest of the noise.

Thanks. I'm going to bury it using a garden hose. I decided I don't want naked coax in the ground 4" down during the winter months.

Bon jour, Msr. Vasile,

I would like a quote for several of your capacitor kits.

Outer diameter 4 or 5 inches (120 mm to 140 mm), capacity of 300 pF max and Voltage capacity of 15 KV. Shipping is to San Diego, California, USA, 92103'

Merci Bien!

Grant.

9005. ALA 1530 Update.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-03-31 19:36:00 UTC
From: ronelltom
Topic: 9005 Message: 9005

Hi all.
Well, I have now got the ALA 1530 Wellbrook Loop on a short mast down the garden. It works superbly on SW (my interest bands). I just cannot fault it for low noise reception of signals. Was it worth the money ?, the answer has to be yes as I had a noise floor of 8-9 24/7 before , and now have an average noise floor of2-3 most days, signals that where usually way down in the noise can now be heard clearly.
I noticed on e-bay that you can buy coils of CCTV cable fitted with BNC plugs for a very low price, (far cheaper than coax and of course you don't have to try to fit BNC plugs to it (I still cannot do it very well). As this cable will only be used for receiving has anyone out tried this cable for receiving radio signals would it be a `good buy' or is there some drawback to using this stuff. ??????
Thanks Guys
Ron, GW1HIN, Aberystwyth, Wales, UK

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-04-01 12:20:34 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9006

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Yahoo allows attachments to posts, and they are automatically placed
in the Attachments folder. The advantage is, assuming this group is
the same as the ten other Yahoo groups I've joined, that the Files
section is only 100 mb of storage. The Attachment (and Photos) folders
are each 100 GIG of storage.

That was a change made to Yahoo!groups, somewhere around three years ago. I have found that it doesn't always work.

Andy

I see no "Attachments" folder. In any case, sending files as an attachment means that someone looking in an Attachments folder in the future would have no context. Can Attachments be organized?

It also means that every time someone sends an attachment to help one or two people, it potentially goes out to thousands.

From: Andy
Topic: 6528 Message: 9011

> It also means that every time someone sends an attachment to help one
> or two people, it potentially goes out to thousands.

The "Attachments" feature that was added to Yahoo!groups a few years ago, works a little (actually a lot) differently.

Yahoo intercepts the attached files from the incoming email, strips them off, and files them away in a special "Attachments" folder under "Messages". The attachments themselves are NOT sent out to anyone, but links to them are. You need to click on those links to go to the group's webpage where you can find the attachments.

Thus, you need to be online. You can't go online, download your email, disconnect from the net, and view those attachments, without going back online again. For many of us who are connected 24/7 that's not an issue; but there are still some folks in the boonies who may not use the 'net that way.

Personally, I prefer having files uploaded to the group's Files and/or Photos areas, where they can be organized and grouped into folders and sub-folders as desired. I have seen some groups with massive amounts of stuff in the "Attachments" folder and it is nearly impossible to find things there.

But anyway, Attachments do not work at all unless enabled for the Yahoo!group, and they have not been enabled for this Yahoo!group.

If it's a concern about trojans, viruses, and such, it appears Yahoo
is doing a good enough job it wouldn't present a threat. I haven't
seen any problems in any of the other Yahoo groups I've joined.

But I don't know the philosophy of this group.

It was just an observation I thought might be helpful. The files
section is 77% full at the moment.

Yes, the attachment folder hasn't been created. Attachments can be
sorted on author, subject, and date.

The attachments folder is a huge help for groups that have maxed out
their files folder. One group has created four additional groups, just
to handle the files.

>It also means that every time someone sends an attachment
>to help one or two people, it potentially goes out to thousands.

Yes, if it's sent to the group. But that might be a good thing.

What kind of "CCTV cable"? Do you mean twisted pair? That may pick up more interference than coax.
I am using old RG-6 coax from cable TV wiring for all my antenna installations. It can be had essentially for free if you know where to look. I picked about 50m on the street on a garbage day. I had to buy a box of type F connectors, a few BNC/type F adaptors and a TV crimping tool.

Works perfectly, no noise pickup at all. A good test is to connect a proper terminator (75 or 50 Ohm for coax, 110 Ohm for twisted pair) in place of the antenna and listen to the receiver. Ideally, you hear nothing at all but the reciver internal noise. Coax of any kind comes close to this, twisted pair picks up a bit.

I'm moving this to its own thread.

I only see these choices:
Store on site (exclude from emails)
Include in emails (exclude from site)
Exclude from site and emails

So I'm going to Store On Site. This makes sense to me, that way everyone isn't receiving every file, but if you want it now or in the future it is available for download.

I prefer files be uploaded to the Files area. When I go to a group, I often just look through files and links.

However, this is not my list. I just run it. I'm setting it to allow attachments and store them on site.

> Exclude from site and emails

I don't know if it needs to be said, but your first choice really has two options:

- Store on site in Files/Photos areas
- Store on site in Attachments area

Me, personally, I prefer the Files/Photos areas, even if they are more limited in terms of the currently available file space that Yahoo gives us. But that's just me.

That option does/did require additional steps, as people need to upload files (separately from sending messages), and others who want them need to navigate online and download them. Whereas using the new Attachments area is more automated because it can all happen within your email program.

Ron,

Sorry I am a bit late commenting on your question.

I can't be specific about using low cost CCTV cable. But I would advise you not to use any cable where the inner core is copper plated steel. Multi-screened cable where there is mix of copper and aluminium foil, silver plated inner core or screen should be avoided in coastal regions as these can corrode and may cause noise.

Best stick with tin plated copper cable like RG58 C/U. This cable is available from Westlake Electronics at very reasonable price. It manufactured in the UK by Webroo (own by Belden).

Hi Ron,

I would second Andy's comments and add that I would be concerned that
the shielding may only be 70% or less and would not fair too good when
used outdoors.

Ron,

I have several years background in both 2-way radio and CCTV fields. CCTV cable (the _real_ kind) is RG-59 for runs up to 200ft or RG-11 for runs up to 2000ft. Typically shield coverage is 75-85% and is copper braid. There is a disturbing trend in the CCTV industry to use RG-6 cable which has an aluminized mylar foil shield. There is 100% shield coverage but the problem lies in the fact that electrolysis occurs in the junction between shield and connector when DC passes through that connection. This results in both desired signal attenuation and problems with rectification (mixing) of undesired RF signals interfering with the video. Baseband CCTV signals do go down to DC and DC current must be able to flow through the shield/connector junction. The other problem with RG-6 for CCTV use is that the aluminumized mylar foil does not provide sufficient skin depth for frequencies below 1MHz or thereabouts. RG-6 was designed for the frequency range extending upward from 50MHz.

I would not have a problem using a good grade of RG-59 (such as Belden 8214) with your antenna. It's 85% shield coverage is adequate for most applications. If you do have undesired interference or noise pickup on the cable it can often be cured by judicious grounding at the service entrance, toroidal or snap-on ferrite chokes to prevent the shield acting as an antenna or, in extreme cases, burying the coax at least 6 inches deep in the ground between the antenna and your service entrance. Keep in mind also that any coaxial cable terminations used out of doors will only have a service life of a few years at best even when weatherized. Degradation is typically very gradual and often goes un-noticed until cable failure occurs. It's best to reterminate the cable at intervals of 2 years or less depending on environment. That also provides the opportunity to inspect the cable itself for signs of dielectric contamination or moisture ingress.

Do you have any pictures of the kits/capacitors?
I'm going to build a loop to cover a lot of bands and need a capacitor with a max value of around 600pf and about 4Kv
How much would that cost in total including shipping to England?

Hi!
Tnx for e-mail!
Here u can see a few capacitors.

http://groups.yahoo.com/group/loopantennas/photos/album/1355109643/pic/list

the shipping can be less then $15.00

in weekend I will do an estimation for yours butterfly capacitor.

Perhaps the capacitance /m miay be more with RG6 cable. I too use the same, ofcourse with PA0RDT mini active antenna.
it is serving me OK with a 25 m cable length to 4th floor terrace.

Instead of aluminum, can you make the plates out of brass or copper sheet?

9024. ALA 1530 now perfect.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-04-03 15:54:38 UTC
From: ronelltom
Topic: 9024 Message: 9024

Hi,
The ALA 1530 is now sited down the garden, and works really well. As I am not still sure whereabouts in the garden to fix it permanently I have mounted it onto a photographic tripopd (from e-bay), making it easy to movbe about different parts until I find the ideal one.
Tracey, G5VU gave me a link to get ready made cables from in the UK at a sensible price,
http://cpc.farnell.com/pro-signal/psg00522/bnc-plug-to-plug-20m/dp/AV14120
Ordered it yesterday and they came today (really feast sedrvice).
So thank you all for the heaps of advice you all gave me.
Best 73s.
Ron GW1HIN, Aberystwyth, Wales, UK

Ron,
Looks a good buy until you get to the ' bottom line ' where
£4.57 becomes £12.62 hi!

There is a simple way to embed photos into messages, without resorting to the Photo or the Files folders.
Open an account (free) on Dropbox, then upload there your photo, then compose your message to the
Yahoo group in HTML, putting in it an <img tag, specifying the Dropbox link as source. Quite easy
to do with Thunderbird. And if you specify the same URL for the Alternate Text of the image, it can
be viewed also by those scared by HTML, who read the messages in text mode only, or by those who
prefer to receive messages in Digest form.

Here is an example. This is a MW/SW indoor loop, built by an SWL and showed at the Renon Meeting of last year.

http://dl.dropbox.com/u/15089947/loop1.jpg

Brian,

no, sorry... I took that photo at a meeting about SDR last year, where an SWL showed his home-built loop. But I have no other data, I don't even remember who was the builder...

I just remember that he claimed a very high Q, and a sharp tuning of the loop, but that's all....

Alberto,
Thank you for the comments.
Using a few ' assumed ' sizes for the plywood and other bits
I guess the diameter to be around 20 - 25 cm diameter.
Does that sound about right from what you recall at the meeting ????
Regards,
72, Brian, GØNSL-QRP.

Brian,

maybe a little more... my hand, wide open, measures about 23 cm from the tip of the little finger to the tip of the thumb.

I guess that the top front side of the wooden cabinet has more or less the dimension of my hand so measured. So the loop itself perhaps is near to 35 - 40 cm. A biometric guesswork.... {:)

9034. CRT Degaussing coil, anybody tried one for a loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-04-07 17:37:05 UTC
From: Phil
Topic: 9034 Message: 9034

Hi All,
I just found an old TV in the dumpster that had it's back off, so I snagged the circuit board (good for parts) and the degaussing coil. At first I passed the coil by, but then on second thought went back and snagged it.

It's resistance reads 20 Ohms, so it must have a fair number of turns in it. When spread out in rough circle it's a bit over 3 feet in diameter.

Question: Has anybody tried using one as an "untuned loop" for LF (perhaps in the 200-530KCs range)? If so, how well did it work?

Phil:

Too many turns close together, distributed capacitance on those is VERY high. Most post-tube degaussing coils are an Aluminum alloy wire that has high resistance so even if you could tune it the Q would be very low anyway.

Might be useful on VLF or ELF since it was designed for 50-60Hz. Unwound the wire is too soft to use as antenna wire.

Hooked up to a 12VAC/1A or better transformer you could probably use it as a degaussing coil...

Thank you Tim,
I was afraid that was the case, but thought I'd ask anyway as the price
was right. Later this summer, before the winter listening season sets
in I plan on building a Varactor remote tuned loop for the 200-530KHz
range, something small enough to fit on a rotator above the roofline,
but large enough to hear something :)

No problem Phil.

I had the same idea years ago when repairing TVs was my bread and butter.

The one I experimented with was out of a 25" Zenith System II (?)
console. The self resonance of the degaussing coil was about 80KHz so
one might be useful for a WWVB receiver.

9040. New USA personal (non commercial) TOA Lightning detection network.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-04-27 22:30:45 UTC
From: compu_friend
Topic: 9040 Message: 9040

Hi Everyone,

(Two loops are used for this Lightning detection system.)

We are starting up a new TOA lightning detection network for private weather stations here in the USA. Europe has a well established system that we are expanding to the USA. In a nutshell, you put up your own detection station that feeds the net here in the USA. The system gives only station owners producing data, any data from the system.
This is a private non commercial system for your use only. The software is free, the hardware is at cost for the core parts. Cables, PS module and such have to be obtained. If your interested in finding out what its all about, start here and look the European system over. They have 412 stations in use all over Europe. We are just starting of course. This is an extension of the European system, so its already operating. It's also starting up in the NZ area. Here is a link to look into it.

http://www.usatoa.com/

Here you will find the USA forum and links to all the other info.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9042. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-01 11:57:56 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9042

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

9043. Remote varactor tuning

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-01 22:41:46 UTC
From: Craig Cochran
Topic: 9043 Message: 9043

I post this knowing it does not deal with loop antennas, but with varactor tuning. I know some members are quite proficient at remote tuning.
I listen to shortwave radio in my car using my portable radio. I have built a resonant antenna. The system consists of a magnetic mount base, a loading coil, and a 4 foot whip. The magnetic mount has a coax feed which goes into the external antenna jack of the radio. Of course the antenna is only resonant for a single band. If I want good reception on another band, I have to change the coil.
I would like to tune the antenna from inside the car using a varactor diode mounted inside the loading coil. I suppose the varactor should be connected in parallel with the coil. (I would like to send the DC tuning voltage through the coax feed line, but I doubt that would be possible when using a magnetic mount antenna. I will use a separate pair of wires if I need to.) But the problem I foresee is my DC line will detune my resonating coil unless I can find a method to isolate the coil from my remote tuning circuit. Would a choke (or maybe 2 chokes) work for that?
If someone knows how to solve this problem, I would really appreciate a schematic of the circuitry.

> Basic Wire Back Yard Loop Antennas
> Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

9045. RE: [***** SPAM 5.1 *****] [loopantennas] Re: File - Links.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-02 20:32:50 UTC
From: David Taylor
Topic: 5136 Message: 9045

Nice list-thanks!

_____

From: loopantennas@yahoogroups.com [mailto:loopantennas@yahoogroups.com] On Behalf Of Jim
Sent: Wednesday, May 02, 2012 3:00 AM
To: loopantennas@yahoogroups.com
Subject: [***** SPAM 5.1 *****] [loopantennas] Re: File - Links.txt

Thanks a lot for compiling all those links. It will make it easier to determine what I need for MW listening. Jim

> Basic Wire Back Yard Loop Antennas
> Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

> TL Loop Receiving Antenna 10 KHz - 30 MHz
> The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

I have often looked into the history of our unique hobby, trying to find out who first patented the idea. And more importantly - the holy grail of the original math behind it. I just discovered this (starting at page 76):

http://www.americanradiohistory.com/Archive-Whites/Radio-Broadcast-1922.pdf

This shows that the fundamentals of loop design were well known by 90 years ago. So far, this is the earliest documentation I have been able to find.

9049. Re: [loopantennas] 90 years of loop antennas

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-04 15:13:10 UTC
From: Jack Smith
Topic: 9047 Message: 9049

Loop antennas predate the 1920s by a long time.

Hertz's discovery of electromagnetic radiation in 1885-1887 used a loop antenna - the transmitting antenna (excited by a spark coil) was a dipole, but he used a loop as the combined receiver antenna, tuned circuit and detector. He called this a "ring detector" but it's recognizable today as a single turn loop.

Greenleaf Whittier Pickard's patent no. 876996, filed June 10, 1907, granted January 21, 1908, covers exactly the subject of a tuned receiving loop - an electrically small closed loop antenna, tuned to resonance with a capacitor. If you read the patent, recall that the term "syntonization" means bringing the circuit to resonance at the desired frequency. This term was widely used in the early days of wireless but has long since dropped out of use.

Lee DeForest's patent 876165, filed May 11, 1904, granted Jan 7, 1908, describes a loop transmitting antenna. In the patent, he notes that loop antennas have long been proposed for receiving but the subject matter of his claims relate to transmitting antennas.

Great find, thanks for sharing.

I have found similar old documents on Google+ under theiir books selection. They've scanned many books which are out of copyright. I've found many historical document on town history, railroads and trolly system and Interurbans.

I just look up a topic and all sorts of stuff comes up.

Best Regards

Subject: [loopantennas] 90 years of loop antennas

I have often looked into the history of our unique hobby, trying to find out who first patented the idea. And more importantly - the holy grail of the original math behind it. I just discovered this (starting at page 76):

http://www.americanradiohistory.com/Archive-Whites/Radio-Broadcast-1922.pdf

This shows that the fundamentals of loop design were well known by 90 years ago. So far, this is the earliest documentation I have been able to find.

Does anyone have more info on the loop system that is on the page marked 22?(link below) ,and directly above that page is another pic that shows an inside loop system.

http://www.americanradiohistory.com/Archive-Whites/Radio-Broadcast-1922.pdf
THanks for the link Bruce :) very interesting stuff

These were built for the signal corps it says ,I'm mostly interested in them for the possibility of building one for my setup ,i've seen this picture before ,maybe in the files section?

I'd really like to know the distances between loops on the roof setup and if they were using a phaser ,and any other details we can find,like what freqs they monitored etc.

The indoor loops look to be about 3 feet in size ,which according to my experimentation is all the bigger they would need to be for AM .

It must have been great to DX back then ? i bet it was very quiet compared to what we have now :)

Most likely they were each for receiving one transmitting station.

They used to "relay" messages through different stations since range was pretty limited by today's standards. Kinda like the internet routers of their day.

9078. 80 meter delta loop a big success on hillside!

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-09 01:59:38 UTC
From: The Desert Tortoise
Topic: 9078 Message: 9078

I really don't know what I want on the home front yet. A totally vertical Delta or square loop which both would fit, or something with a slope? I just put up an 80 meter delta loop in the mountains a bit of way out of town. The wire height from the ground was awful, about 2 feet high on average, but the slope of the loop left the apex about 30 feet or a little more above the base line of the loop. I had the loop pointing approx sth east. I could receive as high in the east as Nova Scotia and as far south as Florida's southern end. I made contact with the Collins user group on 40 meters and was able to talk with both their east coast and west coast moderators with a signal strength of about 5-9 to 5-10 either way. I had reception up into British Columbia and south into some Spanish speaking countries. The southern states also were an easy contact. The only stations I could hear others talking with that I couldn't even hear were those directly north of my position here in Truth or Consequences New Mexico. Colorado, Idaho, and a few others in that direction. I really am favoring the delta loop in a sloped configuration as I could buy one tower and have four loops facing all directions and just switch out the unused loops as needed. I'm going to the same hillside next week to try a square 80 with the same slope. I'll report back on that one for all.... 73's Ron KF5PTJ (New Ham) PS- I hate my call sign, just applied for a vanity... I'll let you all in on the new one if I get it..

Yes, I used something like this wound on maybe an 8 foot length of 3 or 4 inch outside diameter black PVC pipe connected to the Drake SW-4A receiver I once owned. I did not have an antenna tuner, and there was no "top hat" for capacitive loading. It lay on the floor of my apartment, and I was able to do some short wave listening with it. I wound the PVC pipe with magnet wire with space between the turns. It wasn't optimum, but it did work. Bill Young WD5HOH

Ron the delta loop is a good antenna. I am often invited to a club where they have a 80 m delta loop permanently set up - it is magic. At home I only have space for a 40 delta loop it is really good - or was till 40 got crowded out with plasma tvs and other crud producers. The beauty of feeding a delta loop with a balun instead of a matching line of coax is that it loads up perfectly on 80 and 40 or 40 and 20 depending on which band it is cut for. Cut for is a relative term when it come to delta loops they are so broad, they really only have to be in the ballpark. I only use 100 watts and am constantly met with disbelief that I am only running 100 watts, most thinking I must be running linear. The scheme of one tower and four loops sounds really good - the one thing with the delta loop is that it is not rotatable ;(. I spoke to a ham in Russia that had a bi directionally switchable pair of delta loops. He seemed to have a good front to back ratio from where I was listening ;)

Loop Antenna News and Information ForumUnless you are going to use the antenna to transmit, don’t waste your time. The helical winding is just intended
to distribute transmitted antenna current over the length of a very short antenna, better than one typical single
loading coil. It will in no way pull in signals better than a plain wire the same length IF that short antenna’s
high impedance is somehow matched to the typical receiver’s low impedance input.
I remember reading in FRENDX (SW club bulletin) two or three decades ago how wonderful it would be to be
able to use the “Joystick” (brand name) short antenna in a small boat with a SW receiver. More advertising
BS: there just is not any magic to a short wire antenna, or a long long wire wound onto a short mast.
One question tho for the older readers: remember those “AM antenna booster coils” that J.C. Whitney
(for example) used to sell? Somehow they mounted on your car antenna. Since the car antenna, on MW AM
band, is very high impedance, and in fact uses low-capacitance coax for that reason on the lead-in, how
could this loading coil possibly work, and work for a 3:1 frequency range? Maybe it didn’t work! Or maybe
it worked “psychologically” only?

A 160 meters full-wave loop is indeed a vy good antenna, provided you manage to put it reasonably high up from the ground, regarding wavelenght...

The one I used last year was a great performer for close-range (NVIS) QSOs during our 1.8 national contest here in France. It was arranged as a delta configuration, fed in one corner that was 22 meters agl, the two other corners being only 6 meters agl.

I could see there was practically no "cone of silence" effect, so the end of the groundwave range and the beginning of the skywave range must have coïncided in a way or another.

Maybe I should try to model it using MMana... Would you be interested in seeing that ?

I'm a bit sad to see things degenerate here so much. The tone of the moderators slapdown was a bit over the top, I think. We're supposed to be a community, not a rabble. I completely agree that that kind of comment has no place in this forum, but we need to be nice how we let others know when they've gone too far.

I try to avoid holy wars whenever possible. Being behind the screen and not looking the other person in the face seems to bring out the worst in people.

Nuff said about that

I'm still a huge fan of horizontal loops and will continue to experiment with them as time permits (see? I'm on topic after all).

My next project will be to put up a 160M full-wave loop on our new office building in Chantilly, VA. The powers that be have decreed that our yagi will not be welcome at the new digs, so I'm eager to get the new antenna up once we take occupancy.

My little attic-mounted 40M loop's been a joy to operate. Since it's so close to the ground and is twisted around to fit all that wire in one place, I have some real difficulties getting out beyond 6K miles or so, but I'm able to work all the bands from 40M through 10M. 6M is a bit iffy for me, but it works. Kind of.

Later, Gents (and the occasional lady)

Buck,

I believe the loop is probably a multi-turn one using Litz wire. Page 533-53 of Keen's Wireless Direction Finding (1938 Ed.) describes an RCA Radio Compass Type AVR-8 using an antenna similar to one you mentioned. The loop is 8 inches diam. enclosed in a streamlined bakelite housing.

My present loop's only about 20 feet off the ground, but performs pretty well in spite of that. I think the reason may be that the middle of each side has been pulled inwards and upwards so it's more or less pyramid shaped with the pulled in sections at the top are about 8 feet above the corners and are about 3 feet from touching in the middle.

The antenna has four fairly pronounced lobes one of which points directly into Europe.

The new office building is about 100 feet tall, so it should perform fairly well.

Buck:

The one I have is from a Narco ADF-31 system. It's a ferrite disk about 1/4" thick and 4 1/2" in diameter. It has 3 windings of flat copper conductor at 120* from each other. Protection diodes are across each loop and they are capacitively coupled. One of the diodes was shorted on mine causing the factory smoke to escape some components in the receiver itself.

The ADF unit is actually 3 receivers operated through differential amplifiers to drive the indicating selsyn. I have some photos of the disassembled loop but I'm still on my first cup and can't seem to locate them at the moment :(

It's a real pain to get apart since everything is sealed in foam.

9093. Copper-tube RX loop design - questions + .maa file

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-09 11:43:21 UTC
From: Benoît Mangin
Topic: 9093 Message: 9093
Attachments: 1 described; binary payloads are missing from this source WARC

Good afternoon all,

I'm at the same time building my first serious loop project and using MMANA for the first time.

The loop is built as follows: 2,5 meters on each side, made out of 18mm copper tube, elevated 1m above ground, mounted on a rotator. Starting design resonant frequency: 1815kCs (160 meters, single-banded).

Calculations an MMANA indicates 920pF for tuning to resonance (1815kHz). But what amazes me is feedpoint impedance.

I wonder if my tuning capacitance is really put in parallel with the inductance formed by the loop itself. Isn't it in series with on end of the loop ?

Could some MMANA pionneer help me with that ?

I would like the loop to be a nice performer, after having tested smaller and less "thought about" models.

Could some loop pionneer help me with that ? Have you got something to suggest me to further increase the antenna performance ?

I keep in mind that nothing replaces on-field testing, but I can only do that on sundays...

Hoping for friendly answers,

de F8GRY/Ben

Hi, Warren -

Sorry to jump in on a two-way chat. I hope you will excuse my anxiousness in doing so.

I am curious about the use of the delta loop on two bands. Can you tell me if you are using an 80 meter delta loop on 40 meters, as well as on 80 meters, or is it the other way around. I'm trying to get something up in my small lot that will get my signal across the Pacific.

Do you think the delta loop would be better (for DX) than a tpo-loaded vertical? I can only go about 44 feet in height with either antenna.

Thanks, Warren. Have a good day.

73,

Jim, K8OZ

Ron the delta loop is a good antenna. I am often invited to a club where they have a 80 m delta loop permanently set up - it is magic. At home I only have space for a 40 delta loop it is really good - or was till 40 got crowded out with plasma tvs and other crud producers. The beauty of feeding a delta loop with a balun instead of a matching line of coax is that it loads up perfectly on 80 and 40 or 40 and 20 depending on which band it is cut for. Cut for is a relative term when it come to delta loops they are so broad, they really only have to be in the ballpark. I only use 100 watts and am constantly met with disbelief that I am only running 100 watts, most thinking I must be running linear. The scheme of one tower and four loops sounds really good - the one thing with the delta loop is that it is not rotatable ;(. I spoke to a ham in Russia that had a bi directionally switchable pair of delta loops. He seemed to have a good front to back
ratio from where I was listening ;)

73

Warren ZL3LC

I really don't know what I want on the home front yet. A totally vertical Delta or square loop which both would fit, or something with a slope? I just put up an 80 meter delta loop in the mountains a bit of way out of town. The wire height from the ground was awful, about 2 feet high on average, but the slope of the loop left the apex about 30 feet or a little more above the base line of the loop. I had the loop pointing approx sth east. I could receive as high in the east as Nova Scotia and as far south as Florida's southern end. I

made contact with the Collins user group on 40 meters and was able to talk with both their east coast and west coast moderators with a signal strength of about 5-9 to 5-10 either way. I had reception up into British Columbia and south into some Spanish speaking countries. The southern states also were an easy contact. The only stations I could hear others talking with that I couldn't even hear were those directly north of my position here in Truth or Consequences New Mexico. Colorado, Idaho, and a few others in that direction. I really am favoring the delta loop in a sloped configuration as I could buy one tower and have four loops facing all directions and just switch out the unused loops as needed. I'm going to the same hillside next week to try a square 80 with the same slope. I'll report back on that one for all.... 73's Ron KF5PTJ (New Ham) PS- I hate my call sign, just applied for a vanity... I'll let you all in on the new one if I get it..

Andy,
The 1922 ' e-book ' copy in the University of Hong Kong library only has 503 pages !!!!!
The book was obviously expanded in later years / editions hence your page references
from a 1937 copy.
Regards,
72, Brian, GØNSL.

Attachments: 1 described; binary payloads are missing from this source WARC

The file describing the new version of the loop, with a coupling loop 20% the size of the large one, and place 5 cm above the inferior side of the large one.

Sounds better... Is it still "optimizable" ? In terms of feedpoint impedance, of course ?

Would a ferrite-based Z transfo be enough ? Isn't it too "lossy" ?

Ferrite core loss can be nearly eliminated by using Fair-Rite Products
61 material with 125 permeability as described here:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

Just to add, there is Aeronautical Radio by Myron F Eddy (1941). Chapter 12 deals with DF systems. It should be freely available in PDF from here: http://www.tubebooks.org/technical_books_online.htm

72+1,
Nick.

That is right, I need this antenna to be a bit lossy. After all (the comparison ends there...) a beverage is a lossy antenna. But it's a wonderful RX antenna for our low bands, provided you've got space.

In what measure could the capacitor quality alter the antenna's overall Q as a tuned circuit ?

Making it 7 meters on a side, like Sigi gently showed me on a .maa file he sent me, would be perfect. But it's perfectly impossible in my case.

I managed to reach an acceptable SWR by launching the optimization option, but as long as the Q will be so high, the antenna will be useless to me. I can't re-tune the antenna every time I QSY 500Hz !!!

If he is using it for receiving only loss is, within reason, not a serious problem at 160 meters. A receiving loop can be used to null interference and inherently is lower noise than a dipole with regards to your local noise environment. In the receive only case you can use the losses of a more conventional variable capacitor as a means of widening the bandwidth by lowering the Q.

It is worth experimentation with this. Note that if you switch from the antenna to a dummy load and the receiver noise level goes down you are not sacrificing your ability to detect weak signals. General noise levels at 160 Meters from all sources, atmospheric or man made, are actually quite high. Use this fact to advantage on reception. Inserted attenuation helps IMD performance of the receiver, too.

here.
>
> Enjoy reading them, you will see some calcultions on efficiency using caculators from the web. Unfortunatley to get a loop to be efficient on 160m the loop will have to be a lot larger. Loops are generally small compared to a quarterwave and their impedance is very small. Hence that need for large gauge tubes. Copper tubing is preferred and shoudl be silver soldered. Aluminium is more losey with reductions in efficiency of about 20% over copper. You also need very high voltage rated low loss capcitors. These are specially manafactured air spaced with the moving vanes welded to the rotor shaft. Voltages of 3-5kV are often encountered across the capacitors . Additional you need some losses otherwise the Q will be too high and the bandwidth be so small that you may find that it can't accomodate SSB .

GE es TNX info

The loop you are talking about reminds me of loops like the Wellbrook series. Very performant, but expensive and, more than anything else, READY BUILT. That's to say, it only seems to be a matter of cash. Plus, It is really too broadbanded for me, including the preamp.
What could be the common-mode immunity of such a design ? Maybe really strong, maybe pointless, I really do not know.

The problems I have are: Very high Q, ie ridiculously narrow bandwidth. Plus, the need to find a very sharp tuning capacitor, because very small variations of C completely deafens the antenna. I would gladly sacrifice a few dBs gain for increased bandwidth.

Maybe my starting idea was a bit foolish, but as has been told, "the thing" is worth a bit of on-field experimentation, even if at the end it looks a bit different.

You might look up the "RF Pro-1B" antenna. It is not cheap. But it is
a loop of the sort you are discussing. A friend of mine, N3CKH, has one
and loves it. At the very least study it's descriptions and features.
You will likely want to mimic many of the features if for no other
reason than to protect expensive components such as transceiver inputs.

Hi Hue,
Those "Loading coils" did work in my experience, I used a few of them on car radios for friends in Arizona
that could not receive "KOMA Wolf Man Jack" out of Oklahoma even with antenna trimmer set for max gain at around 1400KHz.
I don't know how they worked but they could receive "KOMA" afterwards.

9116. Using CAT cable to feed active antennas, other questions?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-19 17:30:38 UTC
From: Phil
Topic: 9116 Message: 9116

NOTE: I also posted the following on the NDB (longwave beacon) list and so all may not be applicable here. . .

I understand that some folks here have used CAT cable to feed their active whips, with great success. I 'presume' that they used a toroid matching transformer at each end to "balance" the feedline and keep noise down.

It seems that for this loop antenna CAT cable would be ideal as it would provide a twisted pair to carry the signal down from the antenna as well as extra pairs for DC feed and tuning Voltage feed to the loop.

Questions:
1. How successful was the "CAT, cable experiment", how did you implement it, and would you do it again?
2. How did rejection of noise pickup compare to installations using coax cable (the cable run will be about 35 feet, mostly over a sheet-metal awning/roof).
3. Final question. I planned on using NTE618 varactor diodes for tuning (4 of them in series/parallel). I noticed that Dan's Small Parts has the original MVAM108 and MVAM109 varactors in stock for about half the cost. Lyle Kohler (sp?) on his LW site says something about the NTE618 has higher "Q". Comments???

From: Phil
Topic: 9117 Message: 9117

Sorry, only part of the message got pasted in here. The following was
also put up on the NDB list. . .

Hi All,
I'm just now getting ready to design and then order the parts for a
"tunable NDB loop" that will be mounted just above my roof-line. I
haven't figured out the exact mechanical details yet, but am considering
using a "diamond" comprised of a PVC pipe "+" shaped frame to make it
easier to mount on a rotator. Considering something on the order of 3-5
feet maximum diameter.

But the real questions here are on a slightly different subject.
I intend to also post the following on the Loop Antenna forum. . .

I understand that some folks here have used CAT cable to feed their
active whips, with great success. I 'presume' that they used a toroid
matching transformer at each end to "balance" the feedline and keep
noise down.

It seems that for this loop antenna CAT cable would be ideal as it would
provide a twisted pair to carry the signal down from the antenna as well
as extra pairs for DC feed and tuning Voltage feed to the loop.

Questions:
1. How successful was the "CAT, cable experiment", how did you
implement it, and would you do it again?
2. How did rejection of noise pickup compare to installations using
coax cable (the cable run will be about 35 feet, mostly over a
sheet-metal awning/roof).
3. Final question. I planned on using NTE618 varactor diodes for
tuning (4 of them in series/parallel). I noticed that Dan's Small Parts
has the original MVAM108 and MVAM109 varactors in stock for about half
the cost. Lyle Kohler (sp?) on his LW site says something about the
NTE618 has higher "Q". Comments???

From: Tim Hills
Topic: 9117 Message: 9118

Phil:

I've used CAT 5 cable for an active remote tuned/rotating MW/LW loop, yes there is a balun at each end and noise pickup was less than a single Copper shield RG-6 but not quite as quiet as feeding through the same baluns with twin RG-6 salvaged from a Dish system. The CAT 5 is still there but being used for control and signal lines. Mine is mounted in the attic over the garage and the cable runs close to the main breaker box with very little hum pickup with either the CAT 5 or the twin RG-6.

I used the MVAM109s from Dan's and out of the 200 I have bought from him only 12 have been bad though he throws in extras so about 95 out of an order of 100 are usable. Most of the failures are because they get noisy at the higher end of the tuning range but those should make good noise sources. Twice I've caught MVAM109s on the monthly specials and at $0.20/each in bulk they're much cheaper than I've ever found the NTE618s.

I test and match them because they do vary a bit, from 390 to almost 500pF at 1V (most close to 440pF) and 16 to 24pF at 9V. The last batch of 100 I bought yielded 30 closely matched pairs. I've used the 109s with up to 10V to extend the upper range and down to about 0.7V but going outside the 1 to 9V specs can give poor results unless they are tested and stable at those voltages, about half pass that muster. Intermod at both ends and self generated noise at the upper for the most part. Tuning close to a strong MW station at either end of the scale can also drive them non linear.

The tuned loop (Frankentenna) uses 1 pair back to back for MW, ~ 520 to 1750 Khz and relays switch in another 11 pair for LW with the same loop tuning it from ~140 to 540 KHz. The "Q" without any regen is high enough to make tuning very fussy even with a 10 turn pot at the higher end. The single pair is fed through a 100K resistor but to get it to work with 12 pair the other 11 are tuned through an 18K resistor and that does reduce the Q a bit. The loop is 34 CT turns of 100/46 Litz on a 16" overall bundled ferrite. 2 8"x1/2" rods end to end with 6 8" rods around the center two. All the rods are about 125 permeability except one of the center rods with 400 permeability, the deeper and tighter null is off the end with the higher perm. rod. Inductance measures 224uH. An 8 turn CT pickup winding feeds a balanced, gain controlled MOSFET preamp. An Amidon FT50-43 is used at each end with a 1.6 CT:1 turns ratio at the preamp end and 1.5:1 turns at the 50 Ohm receiver output, works quite well throughout both bands. I'd have to check my notes but I think the # of turns is 16:10 preamp to feedline and 15:10 feedline to receiver. Right now it's working but not at all "pretty" but I should have time to finish it now and write it up.

I've used the MVAM109s on air core loops from 60KHz to 10MHz and
preselector, tuning and VCO circuits up to 50MHz with no problems as
long as I avoid excessive RF levels across the diodes.

Hope I answered more questions than caused confusion ;)

From: Jerry Flanders
Topic: 9117 Message: 9119

I use ordinary unshielded cat-5 cable to bring my HDTV signal from my satellite receiver in the den to the HDTV in my bedroom. Two cat-5 cables, actually - 3 pairs of a 4-pair cable carry the YPbPr signals and two pairs of the second one carry the L and R audio. I have about 80 feet of the cables. All works well. All are unbalanced - I made sure I had connected center to center on all RCA plugs to keep the polarity straight.

Before I did this, I researched the isolation and bandwidth ratings of common cable. Looked good on paper, and worked well in practice.

I wouldn't hesitate to use cat-5 cable in any RF application as long as the power level is reasonable - those wires are pretty thin.

As you say, it would be nice to have those extra wires for the tuning voltage, etc, so this cable would be a convenient choice for a loop.

IIRC, a single pair shows 200 ohms impedance, so you could parallel two pairs for a 100 ohm system, or parallel all 4 pairs for a 50 ohm system. A 4-pair 50 ohm line should work nicely as a lightweight feed for a half-wave dipole.

9120. Intro,

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-05-21 14:56:30 UTC
From: g4hds
Topic: 9120 Message: 9120

Hi All,
My name is Paul and my call is G4HDS, i am hoping in the near future to be able to take early retirement, This means I will be moving QTH to the Highlands of Scotland where I can play radio a bit more, and tinker with aerials to boot.... This include's trying to use loops as a low noise option on the LF bands i.e. 160 & 80 for Dxing.

What I would really like are some suggestions about circuit Diags which possibly use small power RF devices to ensure a greater signal level handling without keeling over...

Recent testing whilst house hunting across the border, with a full sized dipole aerial for 160 feeding the rig showed up problems with some of the more modern solid state radios.

Hence the idea to run seperate rx/tx aerials with a low noise loop as the rx setup.

Look forward to any feedback Regards Paul...

9121. ACTIVE LOOP ANTENNA

I have searched some loop antennas for OM, I came across a model made by Wellbrook ALA - 1530. Investigating the e-bay for sale not found, only the manufacturer's website which is in Wales - UK price £ 200.00 there.
A colleague has information about this antenna to the active (benchmark) and if there is a way to get bring it to Brazil?

http://www.wellbrook.uk.com/antennashop/index.php?route=product/product&product_id=59

thank you

Amigos da lista, tive conhecimento de um pequeno projeto para montagem de uma antena loop amplificada que atua na faixa de 100kHz - 30 MHz parecida com a "pa0rdt de Roelof Bakker". Parece-me que um colega do Rio de Janeiro, começou a montar esta antena e até postou em uma lista de discussão do DXCB. Alguém tem conhecimento deste fato e poderia me dar uma pista como entrar em contato com este colega?

I already did RX tests using a copper-tube loop feeding the PA0RDT Mini-whip preamp via a balanced/Unbalanced, just to see.

It appears to me that the loop HAS to be reasonably sized, otherwise there is really too much input voltage on the preamp, an its performance quickly degrades.

Plus, the miniwhip preamp is a very high impedance design, whereas the loop (especially on VLF/LF) is a very low Z device.

The J310 in its Z-adapter config is meant to deal with very high impedances, bringing them to a reasonable level to deal with 50, 75 or 100 devices (preamps, coaxs...)

OR AM I FOOLING MYSELF ?

That's pretty much it in a nutshell. It's probably going to be noisy and not perform very well ... I never could get a decent wideband match with a tuned loop and a FET as the first amp either. (Technically I was using 2 FETs in cascode to simulate a duel gate MOSFET) ... The preamp I made later with a bipolar was much quieter and even worked reasonably well with the tuning caps out of circuit and operating it as a untuned loop. Still other than the ability to null it still wasn't as quiet as the Lankford Push-pull miniwhip I have hanging from the oak tree out front.

Great, we have someone who wants to learn something!

See QST:

April 83 p22
July 84 p45
June 85 p42
January 86, p37
October 86 p27-36
April 89 p22-27
October 91 p21-25
June 92 p71-72

The information in these articles is mostly reliable,
despite being in QST.

Topic: 9140 Message: 9140

The members of the Loop Antennas group may be interested to learn how I use Flag antennas (delta configuration) for receiving trans-Pacific medium wave stations from the Washington State coast. This DXpedition took place at Grayland Beach State Park <https://maps.google.com/maps?q=Grayland+Beach+State+Park,+State+Route+105,+Grayland,+WA&hl=en&ll=46.790276,-124.091992&spn=0.016631,0.038581&sll=37.0625,-95.677068&sspn=39.320439,79.013672&oq=grayland+beach&t=h&hq=Grayland+Beach+State+Park,+State+Route+105,+Grayland,+WA&z=15> , Washington on May 7th through 9th.

The month of May is not considered prime time for either DU (Down Under) or Asian medium wave from the Washington coast, so my "DXpectations" weren't very high for this trip. Besides the sub-par season, we're a few years removed from the periods of excellent medium wave DX heard during the low point in the last solar cycle. I had planned to be content with antenna experiments, figuring I may not hear any overseas DX worth logging.

Surprise! The first night of the 7th (UTC) was indeed a bust, but the 8th and 9th progressively improved--all the way through local sunrise and my last recorded Perseus SDR files just past 1300 UTC.

All loggings below were made with a single delta Flag antenna, oriented at 240 degrees. The high, dense brush in the southwest direction from my camp site prevented me from creating a phased array as I had planned, so I erected the 2nd loop at 310 degrees to hopefully be optimum for any Asian TPs. The two loops were identical except for their bearing (60 ft. base wire at 3 feet above ground, 22 ft. apex height, 1150 ohms termination resistor (modeled in EZNEC... thanks KAZ), and using the excellent "LN" (low noise) version of Wellbrook's FLG100 modules.

This was the first time I've used single delta loops rather than arrays of two or four loops, and the directionality was better than I expected. Check out this audio clip <http://www.mediafire.com/?vwasnolghm7m550> which compares approx. 10 seconds each of daytime reception on 820 kHz, as I switch between antennas. One signal is KGNW Seattle and the other is KORC Waldport, OR. I have used FLG100 modules for years, but I'm enjoying DXing with the upgraded FLG100LNs now. They seem "transparent" in use with no detectable noise of their own.

DX reception on the 8th was modest, but it was all Asian until sunrise approached when reception shifted mostly to Australia & New Zealand. Even during the hours well before sunrise, the Japanese, Chinese, and South Korean stations came in best on the southwest delta Flag... evidently a case of skewed path reception, perhaps due to the disturbed geo-conditions.

The last night of the DXpedition on the 9th was almost entirely mid-band DU reception and most of the signals were logged during the last 1-1/2 hours before sunrise. I did note a few very weak Japanese signals and they were best on the northwest loop, as typical. The ability to

"rewind" the entire medium wave band with Perseus WAV files was again the #1 tool for capturing as much DX as possible, especially when propagation is poor and interesting foreign signals are hard to find. A few photos with captions from the DXpedition can be seen in this folder:
https://picasaweb.google.com/114798392023680237679/GraylandDXpeditionMay\
792012
<https://picasaweb.google.com/114798392023680237679/GraylandDXpeditionMa\
y792012> The folder includes photos of the FLG100LN delta Flag setup. The loggings from this DXpedition (MS Word file):
http://www.mediafire.com/view/?k7k35x175bg2468
<http://www.mediafire.com/view/?k7k35x175bg2468> Of interest may be the audio clip of 2XD Southern Star, Napier, New Zealand (909 kHz) linked from the document. It's a good example of what a single loop can accomplish on a frequency one kHz away from a domestic 10 kHz North American signal. When two of these antennas are phased the splatter can often be reduced quite a bit. I plan to return to the state park in August, at a spot where I'll have room again for a phased array.

Guy,
It was interesting to read of your radio adventure.
Do I understand the antennas Delta configuration correctly,
base 60ft, 3ft over the ground, apex at 22ft ?????
I have a catenary cord between the house roof ridge point and a 35ft mast
90 ft away running North -South.
I my thoughts on your antenna are correct I could hang the loop on the
catenary and revolve it through 360 degrees !!!!!
Particularly as there is the LPL-349.5 beacon just 8 miles away, a real pain hi!
Regards,
72, Brian, GØNSL.

Hi Brian,

You are correct on the dimensions. Others have asked about the details, so I created a diagram that shows the antenna more clearly. Here is the link for download (390kb JPG image): http://www.mediafire.com/i/?gpb6d8vmffdrs91 <http://www.mediafire.com/i/?gpb6d8vmffdrs91> It should work very well on long wave also.

These basic delta dimensions have been used by myself and a number of my MW DXing pals for single delta loops and phased delta loop arrays with Wellbrook ALA100, FLG100, and K9AY hardware over the last few years. I believe that the specific proportions originated with Andy Ikin of Wellbrook through EZNEC modeling, perhaps with some assistance from Neil Kazaross. Both of these gentlemen have been key players in the optimization of Flag antennas for medium wave use.

It's my understanding that this design (FLG100LN + 1150 ohms Rt) is electrically a Flag, but needs only a single center support due to the delta shape. That fact alone is a big "win" for DXpeditions, as you often contend with limitations of the terrain, conveniently (or inconveniently :^) spaced trees, brush & bushes, etc. that restrict the antenna placement.

If you are indeed able to build a rotatable delta Flag as you have described, please share photos and details with the group! It will be very interesting to learn how it performs for you.

73,

Guy Atkins

Guy,
Very many thanks for the response to my query on your antenna.
Having established the facts as I assumed my problem is that though I have
90ft North / South the garden is only 50ft wide !!!!!!
This of course means that it would not rotate totally from a hung point
as per your sizes.
I assume on the good side a single element loop does not need to rotate through
360 degrees but only 180 degrees ?????
Trial and error is needed hi!
Thanks again,
72, Brian, GØNSL.

Have you looked over my experiments regarding coil Q versus gaps between stacked cores to form rods. It is in the Popelish file folder and called "Experiment_Q_vs_F_vs_GAPS_5z.pdf"

Your material is better than the high frequency material I used, but the general pattern of result may apply, especially at the higher frequency end of the test spectrum.

Hi Brian,

Don't forget that this antenna is a version of the Flag, so it has a cardioid pattern. If your space for the rotation/repositioning is limited you'll want to aim the null at your pest station, or the forward beam towards your DX.

Alternatively, you could reduce the 60 foot baseline to 50 feet, then you can move the delta fully through 360 degrees. I don't think performance will suffer much.

73,

Guy

I've built 2 versions of the delta loop with termination resistor. The first had an 8 ft baseline and 6 ft apex located on top of the roof rotated with a RS rotor and gave a nice cardoid response with deep null. The second one was a 53 ft perimeter, 16 ft baseline with a 17 ft apex on top of my 45 ft tower and rotator capable. The termination was remotely adjusted using a homebrew RS LED and non-inductive photocell. This antenna could only provide about a 30 dB null depth from a local 50 KW flame thrower 8 miles away. The null depth varied with the wind.

Hope this helps.

Alex

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio
Reception, can spend $100 or less and get an AM Loop Antenna that
meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or
less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9151. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-06-01 11:59:01 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9151

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

9152. Can You ID this loop?

Hi,
I bought a very nice old loop antenna at a estate sale. The workmanship is wonderful, dovetail joints,etc.
It has a logo that looks like DTW (the letters run from top to bottom)
It also had a terminal block to enable different frequencies.
Someone at the sale thought it was German. I have done a web search for DTW, but have not come up with anything.

Thanks, Jussi

I assume you are speaking of a "small transmitting loop" or "magnetic loop" antenna.

Here is a 70% efficient magnetic loop for 40m. If you look at the dimensions of that antenna, you will immediately see that achieving that level of efficiency at 40m is not a trivial task.

http://www.qsl.net/zp4kfx/Antenne/Magnetic_Loop.htm

Running only 1 watt, it's going to be a challenge to get a significant portion of that 1 watt radiated and not turned into heat. You'll need to minimize ground losses, capacitor losses, resistive losses, and coupling into other nearby conductive structures.

Running some quick numbers in AA5TB's loop calculator spreadsheet, a quarter-wavelength loop (10m circumference) made of thick conductor (1/2 inch or 1 inch copper pipe), resonated with a low-loss capacitor (butterfly or vacuum variable) might get you above 70% radiated power, assuming ground losses and environmental coupling losses could be minimized.

Good luck!

9162. 6 meter (50 Mhz) horizontal concentric magnetic loop

Yahoo group: loopantennas (2008 — 2012)

Inspired by this project
http://www.aricollialbani.it/files/I5MSH%20-%20Hi-Q-Loop%20per%20i%2050MHZ1.pdf , I built my magnetic loop for the magic band. By the way, the experiment was made with loop horizontally mounted to get omnidirectional radiation and horizontal polarization.
I made a mistake cutting the coupling loop too long.
I tried adjusting the impedance by varying the intersection of the two planes, but it was too tricky.
I tried moving the small loop far from the perimeter and I've found 50 ohm position with the coupling loop in the center of the main one.
http://xa.yimg.com/kq/groups/12851910/sn/1167630074/name/DSC_2457.jpg
See in the picture the miniVNA measuring.
http://xa.yimg.com/kq/groups/12851910/or/692274669/name/loop+6+mt+miniVNA.JPG
I5MSH correctly said, "you can get the same curves with a dummy load".
So, I had to try it on the air. I went on Monte Folgorito, about 900 meters in north-west tuscany, and got 55 from Denmark in SSB, during E-sporadic opening.
Height from the ground 1,5 meter. Few centimeters of RG58 acted as tuning capacitor. Yaesu FT817 with self contained batteries.
Since I'm not a pro in this field, please feel free to leave your comments and evaluation on this kind of coupling, regarding radiated power and far field plot, comparing to "traditional" couplings (close to the main loop, opposite side of the capacitor).

Gaijin (been to japan?)You must be a real QRP addicted.
Maybe I wasn't lucky. I could not get anybody picking up my CQ in 17 meter with 2,5W in SSB with my magnetic loop. To be honest I was on the sea-shore and maybe the gray-line was already too far.
On 6 meter and same power I was lucky at first attempt (a post about this is beeing moderated right now).
Efficient low bands magloops are huge and operated with lot of watts...
Please let me know your achievements.

I'm using a 817 into a DCTL loop that I made from copper water pipe .
Because of personal physical limitations the loop stands against the wall in my room yet it still outperforms the G5RV outside. I think that the better performance is also due to the loop being rotatable where as the G5RV is fixed in location.
The original DCTL design was made out of 300 ohm TV twinlead but I'm thinking of trying one made from really heavy duty twin stereo speaker extension cable. The 300 ohm TV twinlead version was inefficient.
The secret is certainly in efficiency but then the "Q" is so sharp that I have to retune if I move too far off frequency.
I can post pictures of my copper pipe DCTL if anyone is interested.

No achievements to speak of as yet. I am preparing my station for my first QSO (which will be CW), and am still looking for the best antenna solution for my small balcony attached to a concrete building. The rig is an FT-817 with a maximum of 5 watts out. I'd like to get on 40m, as that band is always hopping with CW activity day and night here in Japan, but as was mentioned earlier in the thread, making an efficient small antenna (magloop or otherwise) for 40m is a challenge, especially for QRPers. Personally, I may end up buying a 50 watt amp and use a compromise magloop or short dipole antenna (which will bring my effective radiated power back down to QRP levels).

Like the original poster, I'd be very interested in hearing success stories or recommended (loop) antennas for 40m QRPers, but I suspect the only way will be to follow the normal practices of making the antenna as large as possible, and locating it as high as possible, and as much in the clear as possible.

I've recently been thinking that if one is determined to work QRP, on 40m, with a small loop antenna, then the only saving grace can be a good location, achieved through portable operations. With a QRP rig and a portable loop antenna (even if terribly lossy), a good location like high on a mountain top or over salt water might be able to get enough power radiated and at the right angles for some QSOs.

Hi,
I have built a skywire loop as per the http://www.k5rcd org/hor%20loop%20instruct.htm and the ARRL Simple and fun Antennas book . I find its performance on 80 mtrs disappointing ..

I have it feed with 600 home made feed line which is 71 feet long, 25 ft down the pole and 45 ft to my anchor point on the house and has about 8 mtrs of 213 coax attached to get me inside to the tuner

I have 272 feet plus of wire up and each side is around 73 feet at about 33 feet off the ground,

I did have a 4:1 balun but it was suggested that I take this out so at this stage its out ..

I am running a TS 590s and it appears to be ok with it tunes up good but when I use the MFJ analyzer it tells me its best at 2.900 way off the 3,6 , 3.7 I was looking for

I have set up as per K5RCD a multi band loop ..

Do I shorten it to get it close to 3,6 etc or do I let the tuner do the work ??

Greetings,
I recently fabricated one one of Everett's stacked toroid loop sticks as I wanted something high performance and relatively portable. I also wound the 3 litz coils on clear plastic forms to allow for interchangeability. The only difference that might affect performance, compared with Everett's, is the litz wire I used has fewer strands, (180 vs 330). I have copious quantities is why I went with it initially. Now that it's proven. I'll have to wind some higher count ones. I got lots of the forms too. As far as it's performance, I will back up Everett's claims, at least om MW, comparable readability with less noise. In one case, Readability seemed better, i.e. barely audible muddy signal was more readable.
This station is actually a Travelers Information Radio Station at 530 KHz. I calculated it is located about 25 miles out. Not sure of the power, but they're not allowed more than 10 watts out. They also employ a low-pass filter that rolls off at 3 khz. Hence the poor audio quality. My 2.5 ft octo air loop picks it up fine... along with plenty of noise. The noise was noticeably less with the STLS, but the signal just as strong and a bit more readable. Mind you this is using the smaller litz. The receiver I used, for the most part was a Tecsun PL-230 as it performed the best for its size. I will put pictures of the test components in the photos section. Also plan on long wave testing as soon as I wind the larger litz coils. His wind counts are dead on. This contra wound loop is worth pursuing...

73,
John

9177. small 160m rx loop and ferrite

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-07-03 19:35:54 UTC
From: Sam Morgan
Topic: 9177 Message: 9177

I'd like to ask about what ferrite mix to use at the feed of a small rx loop I
have built

this is NOT a shielded loop
with the break in the shield half way around the loop

I made the loop out of the 2 turns of 5/8 inch hardline I had available
the circumference is about 12'
I am using only the shield as a continuous 2 turn loop

for the feedline I just attached a 50 ohm coax with the
coax center to one end of the hardline shield
and the coax shield to the other end of the hardline shield

it worked fine for what I wanted
in the sense that it allowed me to null
some thunderstorm crash noise during the Summer Stew
allowing me to diversity receive with my outside vertical on my K3
(it even works on 80m and 40m, so the toroid needs to work 160m-40m)

however the pattern is not symmetrical
(I think this is due to the unbalanced 15' of direct coax feedline?)

so I think my next step would be to use a toroid as a balun
with each end of the hardline loop attached by a couple of turns on the toroid
and maybe twice that many turns on the other side of the toroid
going to my 15 feet of 50 ohm coax to the rig

I might later get around to building a preamp for it
but for now all I want to do is add the toroid
in the hopes that it will maybe make the pattern more symmetrical

if I understand this correctly
I am wanting to use a broadband coupling FTxx-xx ferrite core
rather than a narrow high Q like I would get with powdered iron Txx-xx core

I have an FT240-31, as well as FT37-61, and a FT50-61 on hand in my part bin.
they were left overs from an order from Tony at
http://partsandkits.com/toroids.php

I used all the hard line I had on hand
so different lengths, configurations etc etc etc
is not my question, for now.......

for now I just want to know what mix toroid I need to use
between this loop and the coax feed to it
I'm going at this as a step by step learning experiment

I was planing on 4 turns on the primary and 16 turns on the secondary
my reasoning being that might also give me a little signal increase as well?

perhaps later I might get into the matching aspects of this experiment
but I had plenty of signal strength using the coax directly
with the loop setting in my 'other room' of my ground floor apartment
I just thought it would be nice to have a symmetrical pattern
rather than the odd ball one I have now

9178. Shielded loop with Wellbrook ALA100LN

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-07-03 20:49:57 UTC
From: Ron
Topic: 9178 Message: 9178

Hi all,

Since past sunday there was a transmission from SAQ in Grimeton Sweden on 17.2 khz i decided to make a new antenna.

I had a flag antenna with a home build balun and a dx-engineering rpa-1 amplifier and repaced the balun with a Wellbrook FLG100LN module. Sadly it was at the end of the TA-MW season so had only a short time testing this antenna. Last sunday i received SAQ with a S/N of 12 dBm for the first time in my life and with this flag.

In a hurry i made a 30 meter shielded delta loop with RG6 coax and a new ALA100LN module. When SAQ came back on the air for the second time the signal was received with 26.3 dBm S/N. A vast improvement on the flag antenna. On monday i had the time to ground the loop shield and got a 4 dBm lower noise level but and received signals did not suffer. The delta loop is only 1.2 meters above ground and the highest point is 5 meters. I live at 5 meters ASL with a moist clay soil under my antennas.

I noted Andy Ikin from Wellbrook mailed me, that the ALA and FLG modules were not designed to perform so low in frequency but they effectively do so. My beverage pointing in the same direction had only 8 dBm S/N and my MiniWhip did not hear the transmission.

From: gareywittich2000
Topic: 9180 Message: 9180

From my reading there are 4 Basic Toroid Core Winding Methods:

1) Bifilar Winding Configuration
2) Overlap Winding Config.
3) Autotransformer Config.
4) Opposite-Side Winding Config.

What are the ADVANTAGES/DISADVANTAGES of each and WHERE/WHEN should each be used ????

Always learning,

Bifilar (and trifilar) are best when the wire size makes it practical, meaning being able to keep the wires close to the core surface. There is a minimal amount of coupling to the core with this method, and the core provides "magnetization inductance" which extends the low frequency cutoff of wideband transformers. This method also has the lowest degree of losses.

Not sure what you mean by "overlap". I'll assume that you mean winding the turns amongst each other while keeping everything in a single layer. This is slightly less than with #1 and is best used when the wire size makes #1 impractical. The windings should be designed so that the entire core is used with little to no space between the wires, which will minimize coupling to the core.

For #3, I'm assuming you are placing the windings end-to-end on the core. The performance is somewhat less than with #2, and again the wires should use the entire core.

#4 is the worst of all as it results in the highest degree of coupling to the core, which can result in IMD products due to hysteresis nonlinearities as well as higher loss levels.

Take a look at my online paper (and some of the references) for deeper details:

http://www.home.earthlink.net/~christrask/Wideband%20Transformer%20Models.pdf

9189. Re: Shielded loop with Wellbrook ALA100LN

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-07-08 17:59:38 UTC
From: enriqueeeeee2001
Topic: 9178 Message: 9189

Hello Ron,

Quite sure that my ALA 100LN will arrive this week. Just a question,according to the Wellbrook site this antenna can be used with 8-20 metres of wire.
You say that have made a 30 m loop, Have you noted any distortion or overloading using this lenght?

By the way, I am going to use 2,5mm electrical multi wire to make a 23 m loop.

Nowadays, I am using a Wellbrook 330S I hope with the 100LN I will able to pick up more weak stations on the tropical band.

Cheers.

OK there is an official thread on the Yahoo help site here:

http://help.yahoo.com/communities/index?page=forums&topic=679f4462f0374ad181e2a94d6972d4e8&forumname=Known%20issues%20and%20FAQ&topicname=%28KNOWN+ISSUE%29+Daily+Digests+displaying+one+word+per+line.

I just fixed one of the emails by deleting some offending 's from the end of the 2nd message... took me less than 5 mins to fix - Yahoo with all their wealth and people "on it", makes you wonder what they are doing.... I have posted a response to that thread but so far it hasn't shown (not sure if posts are moderated or if they don't like URLs as I sent them a link to a fixed email).

For those who are interested this is the last digest I have fixed:

www.lrgsoftware.com/mike/yahoo_groups_mail_fix.eml

Hopefully this Group allows URLS :)

Date: 2012-07-09 17:08:28 UTC
From: Ron
Topic: 9178 Message: 9196

Hi Enrique,

Congratulations on the purchase of the ALA100LN! No I cannot say that i notice any overloading or distortion with the 30 meter coax nor as i was using 30 meters of wire before that. My strongest broadcast station is 65 km from my home and produces a -21 dBm signal on my perseus SDR.

If you can, try to use a shielded loop as it gives you 4 dBm more S/N as with a wire. Also try not to use 2.5 mm electrical wire as it tends to stretch in time. Use copperweld or as i do use some military grade telephone wire witch has stainless steel and copper strands. It will last a lifetime!

I will however mount the shielded loop on my roof with a slightly smaller size loop to stay there permanently as the now used antenna is a temporarily setup.

Good luck with your new antenna.

Hi All,

Also use the largest diameter wire that you can - it helps and I've done
it on my ALA-100L's.

Topic: 9198 Message: 9198

I'm lost when it comes to loops but I found this. I don't remember where but it might help someone.
Look in the file section the name is HF antenna cookbook
and it is by Texas Instruments..

Nice!

I took the space out of the file name so it is easier to link to it, and changed the capitalization.

http://groups.yahoo.com/group/loopantennas/files/AntennaCookbook.pdf

It is about HF RFID tag readers, which operate at 13.56MHz so it is a great loop antenna reference.

The webSDR of the Univerity of Twente has been inactive since november
because of lack of an antenna facility.
It's back on the air right now!,

WebSDR on eight bands <http://websdr.ewi.utwente.nl:8901/>
http://websdr.ewi.utwente.nl:8901/

During its absence I have been listening to:

The experimental WebSDR located at PA3FWM's home
<http://websdr.ewi.utwente.nl:8903/> http://websdr.ewi.utwente.nl:8903/

This is also still active and worth a try.

It is a good thing you archived this document here, the RFID group at Texas instruments was shut down over three years ago - everybody went in the massive lay off they had. I don't know how long it will be before TI shuts off the applications material for RFID. They tend to do a pre-frontal lobotomy on applications material they deem outdated / not applicable.

Thank you Ron and Don for the advices,

I have already received the ALA100LN, next week I will try it.

Regarding the wire, I have been surfing the web and some people recommend twimax 100 Ohms cable, it is shielded has two wires that in parallel are 50 Ohms. I think that is a better option than the 2,5 mm electrical wire.

By the way, since I am going to have two antennas,a Wellbrook 330S and an ala100LN I would like to get a phaser in order to null some interferences that comes from the elevator.

Anybody knows one that covers both MW and SW?

Best Regards

Juan,

The ALA100LN I sent to you was a special extended HF version (JFET/Bipolar cascode). Therefore, there may be a problem with loop to screen capacity slugging the HF responce. I would recommend that the keep the loop to 8m circumfrence or smaller is MW overload is an issue; 2.5mm sq. wire is okay.

At HF the loop size will affect the loops ability to reject near field electrical noise, so the smaller the loop size the better.

73

Andrew

9204. Re: Shielded loop with Wellbrook ALA100LN

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-07-12 10:24:41 UTC
From: Ron
Topic: 9178 Message: 9204

Andrew,

On this moment the ALA100LN - shielded loop is my best antenna besides my beverage, the 10 by 4 meters FLG100LN is the inferiour antenna at the moment. All antennas are pointed in the same direction but the shielded loop has no attenuation on the "back" side of course.

How is the JFET/Bipolar ALA100LN different from the standard model?

My ALA100LN has no problem with strong MW signals. My strongest station is -16 dBm at night with the 30 meter coax. I have however connected the coax shield directly to a separate earth right under the antenna. The coax is a RG6 with a solid aluminum shield and a normal woven shield to double it up. I did receive the SAQ signal with a S/N of 12 dB on the FLG100LN and 26 dB S/N on the shielded ALA100LN loop. Signal strenghts on both antennas was the same. I remember you mailed me that the ALA and FLG amps where not designed to recieve so low in frequency but obviously they do a good job at it!

73' Ron

Hello Andrew,

I will try with a single loop (8 m) and with two turns (4x4) in the same pole I have the 330S.

Any chance in getting your old APU-100 antenna phaser? I would like to get one for MW and SW.

Kind Regards.

and still waiting...
What's the point in someone advertising something saying how good they are, waits a few months and posts it again, and then posts on other places as well yet never comes back with a price
Pointless.

Ron,

The ALA100LN has higher gain than the FGL100LN Flag antenna because the Flag has a higher loss due to the termination resistor. The Flag antenna loss is approx. -10dB per octave. That's why the gain drops off significantly at low frequencies.

The JFET/Bipolar version of the ALA100LN just has more gain above 10MHz due to the reduction of the FET Miller capacitance; by using the transistors in cascode.

73

Andrew

Subject: [loopantennas] Re: Shielded loop with Wellbrook ALA100LN

Andrew,

On this moment the ALA100LN - shielded loop is my best antenna besides my beverage, the 10 by 4 meters FLG100LN is the inferiour antenna at the moment. All antennas are pointed in the same direction but the shielded loop has no attenuation on the "back" side of course.

How is the JFET/Bipolar ALA100LN different from the standard model?

My ALA100LN has no problem with strong MW signals. My strongest station is -16 dBm at night with the 30 meter coax. I have however connected the coax shield directly to a separate earth right under the antenna. The coax is a RG6 with a solid aluminum shield and a normal woven shield to double it up. I did receive the SAQ signal with a S/N of 12 dB on the FLG100LN and 26 dB S/N on the shielded ALA100LN loop. Signal strenghts on both antennas was the same. I remember you mailed me that the ALA and FLG amps where not designed to recieve so low in frequency but obviously they do a good job at it!

9209. Power Supply Question

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-07-16 11:43:45 UTC
From: Ralph
Topic: 9209 Message: 9209

Gents,

I've built a 5' square loop, framed in 1" PVC and amplified via a Ramsey AA broadband amplifier. In tests so far, it has provided me very nice, clean signal-to-noise compared to my longwire antenna.

I have situated the loop about 50 feet from my house, away from any sources of electrical noise (my biggest goal).

Right now, the amplifier runs off of a 9v battery, so this is not a workable permanent situation. The battery drains down in a few days of use. I certainly don't want to have to be going outside during the winter to change batteries on the amplifier unit!

Question: If I use a 9v DC power source (hundreds of them are available on Amazon), will (a) this create noise at the loop, defeating the main goal of the remote loop? and (b) can I run the DC power line 50 or 100 feet to the antenna -- will this weak current dissipate over that length of wire?

I am aware that somehow the Wellbrook loops supply DC power to the remote loop, so I suspect I indeed can feed this with a lonnnnnnng DC power line, but would like confirmation from others' experience.

Regards,

Ralph

Even wire as small as used for a doorbell would carry this small current for 50 feet with only a fraction of a volt lost to resistance. And that can be made up for by starting with a slightly higher supply voltage. But most RF amplifiers are quite tolerant of small supply voltage errors, either way.

I would find a simple transformer, rectifier, capacitor type supply, not a switching regulated type, to keep the RF noise low. You may want to add a solid state linear regulator, but that would best be placed at the amplifier end of the wire. Don't forget to add a capacitor to the input end of that regulator (at least twice what the data sheet says is minimum), to suppress its tendency to oscillate when fed from a long wire (highly inductive source).

You could run the 9vdc on the coax and block it at both ends with capacitors so it does not enter the RF out of the Amp or the RF input to your radio.

From: Benoît Mangin
Topic: 9212 Message: 9212

Good evening all,

I'm in trouble using all my loop calculation softwares under windows seven. My favorite, rjeloop3 (from the zerobeat download page) just does not open.

What do you use for your multiturn loop calculations (softwares) ?

I could use the thomson formula, but I also want to approach the thing with the use of softwares. I haven't got any mini-VNA, nor do I have a precise enough inductance and capacitance meter (mine does mesure @ abt 1kHz frequency, which I do not find useful for RF design).

It's a PIC-controlled LCmeter I ebayed myself couple of months ago. Do you think It could be useful nonetheless ?

Do some of you use some Windows7 friendly loop calculators ?

de F8GRY/Ben

> What do you use for your multiturn loop calculations (softwares) ?

Are you talking about a small loop (magnetic loop) antenna?

If so, I use 4nec2 for this sort of thing. It can load EZNEC files. The following post contains an EZNEC file of a multi-turn loop:
http://www.eham.net/ehamforum/smf/index.php/topic,83624.msg603106.html#msg603106

As a fully-featured NEC2-based antenna modeling suite, 4nec2's features may seem overwhelming at first, but it's actually very easy to use, and I'm sure it gives you far more information than a simple loop calculator program would (information like current distribution around the loop, 3D radiation pattern, etc.).

OK,

For modelling purposes I use MMANA, because of the graphical functionalities of the thing. But modeling a octogonal 25 turns 2m diameter loop takes some art...

Plus, the loop should be made with litz wire (for LF/MF use or MF/160meters use), so modeling is out of the question, because of stray capacitance of such a cooil. All I have to do, I guess, is build, then measure, then apply Thomson formulas. But it is in the peasuring part that I doubt the thing. My LC-meter just seems not reliable enough to me, for RF applications. I guess it samples the inductance es capacitance @ 1kHz.

I would like to build it for 100-600kHz or 400/2000kHz use, which can be a bit tricky...

Have you got any measuring procedures ? I do not care about SWR at this stage, this will be dealt with using proper ferrite transformer and/or coupling loop inside of the main - that's to say, tuned - loop arrangement.
I will need to get L of course, and C, due to Litz wire use and the increased stray capacitance it produces. Then, I could get the antenna self-resonant frequency -without connecting a capacitor - and calculate how much C I need to resonate it on other frequencies.

Any suggestion ?

> What do you use for your multiturn loop calculations (softwares) ?

Are you talking about a small loop (magnetic loop) antenna?

If so, I use 4nec2 for this sort of thing. It can load EZNEC files. The following post contains an EZNEC file of a multi-turn loop:
http://www.eham.net/ehamforum/smf/index.php/topic,83624.msg603106.html#msg603106

As a fully-featured NEC2-based antenna modeling suite, 4nec2's features may seem overwhelming at first, but it's actually very easy to use, and I'm sure it gives you far more information than a simple loop calculator program would (information like current distribution around the loop, 3D radiation pattern, etc.).

9215. Re: Shielded loop with Wellbrook ALA100LN

Hello,

I have already intalled my ALA 100LN on the roof. It is a 21 m loop in a single turn. It offers a big signal on MW and LW frequencies, I would need more attenuation on most of the cases , I have s external one but I would like to know if there is a lineal potentiometer or similar that can work as an attenuator.

My next step it is to build a 2X 1,5 m frame with three turns of wire, maybe this configuration will work better, but I want to keep the 21 m loop for weak signals.

I have tested this ALA with my 330S and I have realized how good is the latter on the SW segment.

Regards.

>
> How is the JFET/Bipolar ALA100LN different from the standard model?
>
> My ALA100LN has no problem with strong MW signals. My strongest station is -16 dBm at night with the 30 meter coax. I have however connected the coax shield directly to a separate earth right under the antenna. The coax is a RG6 with a solid aluminum shield and a normal woven shield to double it up. I did receive the SAQ signal with a S/N of 12 dB on the FLG100LN and 26 dB S/N on the shielded ALA100LN loop. Signal strenghts on both antennas was the same. I remember you mailed me that the ALA and FLG amps where not designed to recieve so low in frequency but obviously they do a good job at it!

Hello Brian,

Spaced at least 3-4 inches and triangular in shape. 6,3 metres each turn, maybe I will have to use two turns if overloads.

I will start the project tomorrow morning.

Regards.

Hi,
Thank you for the mail and comments.
Having acquired an ALA-100LN last week from Andy it is similar to the idea I have for a rotating antenna.
I will send you a photo when it is built if you wish ?????
pass along a direct e-mail to me.
Best wishes,
72, Brian.

9220. Re-wind a ferrite rod AM/FM Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-08-16 21:58:24 UTC
From: David
Topic: 9220 Message: 9220

All,

I restore antique radios, and the one I opened up last night has a problem I haven't seen before. The Ferrite Rod antenna broke lose and some of the windings un-wound. In addition, the insulation on the windings is damaged in places, so I'm thinking the best option is to re-wind the antenna. I'm curious though how many windings there should be, and what guage wire to use and what spacing is appropriate. Because the antenna has unwound itself, I can't just replicate the number of windings that were on there...I don't know how many were originally there.

It seems the windings at each end have no spacing, while about 4" near the center have about a mm of space between each winding (2x wire guage).

The Ferrite core is 6 3/16" long and 1/2" in diameter. I think this antenna is used for both AM and FM, only but not 100% confident of that. There appears to be only two connections from the antenna to the radio. I assume the ferrite core is type 61 based on the fact that it is in an AM radio.

Any advice you can give would be much appreciated.

Dave Castor

Hi Dave,
Perhaps you could meaqsure the length of the wire that came unwound from the rod. Together with the diameter of the rod you can calculate the maximum number of windings that that piece of wire could have occupied on the rod. Perhaps you can also determine the distance that piece of wire had from the rod it was wound on to the electronics it is or was soldered to. This may help you to refine the estimated number of windings on the rod.
I hope this helps.

Cor Beijersbergen

Even if some of the windings came loose off of the ferrite rod is the wire still there and intact? You could take the wire and rewind it over the rod just so you could re-count the number of turns. It doesn't have to be neat. All you want to do is recount the number of turns of wire. Once that is done you could order some new wire and try again.

Depending how much of the original wire is still on the rod, if you could count how many turns of wire there are per inch of length you could come up with a pretty good guess of the size wire used. Most wire charts have the number of turns per inch. I would guess they must have used extremely fine wire like #34 or smaller.

That would be the way I would approach the problem. You should be in pretty good shape as long as the original wire is still intact. You may need
some good patience to work with extremely fine wire size. You can stretch coiled-up wire out to a straight length again to try and count the number of turns as long as it is not kinked up badly.

A ferrite rod antenna would only be used for AM reception, not FM.

I considered that idea, but it's not clear how much was previously wound on the core and how much was used as a lead. I haven't been able to determine where the antenna was mounted so the distance to the mount point doesn't help either.

I should be able to follow Steve's advice...I'll let you know how it turns out.

If you have one of these towers you might be interested in joining a new discussion group, here is a link:

http://groups.yahoo.com/group/CrankupTiltoverTowers/

Regards, Al / NN4ZZ

Here is some info about the discussion group:
****

Crankup and tiltover towers are becoming more popular for several reasons.

- the safety and convenience of working from the ground

- many hams don't want to climb guyed towers any more

- many of popular new antennas (e.g. SteppIR, Ultrabeam) require more maintenance

This group is open to all amateurs interested in these towers and offers a place to discuss the vendors, tower options, installation, and accessories.

The mission for this discussion group is to provide a focal point to share your experience and questions.

Hi Rick,
Nothing wrong with tower talk but the new group is just for tiltover towers. There seems to be a lot of interest in this subset. We have added over 100 members since launching yesterday morning (adding a new one every 20 minutes or so)

The yahoo group format is also nice for pix, links, etc.

Thanks for the correction. I had no idea ferrite rods could
be usable at VHF frequencies. Would those be some kind of
miniature ferrite rods? I still don't think a regular ferrite rod
like what would be used on a typical AM/FM radio
perhaps 5-6 inches long would be practical on VHF?

Hello Abdullah and others,
There is an awful lot of information about building loop antennas for the AM BC band on the net. I hope you have good access to the net.
Try "AM loop antenna" in Google and you will be busy for the next couple of days reading it all. I tried it again and on the first Google results page I found among others the following relevant pages.

http://www.mtmscientific.com/loop.html
http://www.iw5edi.com/ham-radio/files/AM_loop_antennas.pdf
http://www.frontiernet.net/~jadale/Loop.htm
http://www.dxzone.com/catalog/Antennas/Loop/
http://www.eagle3.net/n4ywn/docs/Am_Loop_Antennas_2004.pdf

In the last PDF file youi will find several construction descriptions. There must be something for your needs in it.

Regards,
Cor Beijerbergen

Dear Sir,

GE Abdullah,

Maybe could you tell me a bit more about your project...

What would you like to use your antenna for (local radios ? DXing ?) ?

Available space ?

Do you use preamps ?

Are you in a noisy location, RF-wise ?

What are the material you already have available (wood, PVC, wire) ?

What are the main things you would like to get (proper nulling ? High output, ie Gain ?)

Have you got an idea of the design (single turn, multi-turn, shielded or not ?)

How would you like to get it tuned : Variable capacitor ? Varicap diode for remote tuning ? Broadband ? Untuned ? Band-pass ? You could make you loop as part of a filter design, so it can be low pass, band pass, high pass...

I'll gladly help you, so do not hesitate to e-mail me, even off-list if you wish.

I can even take time to model your antenna-to-be using antenna modeling software.

Dear Benoit Mangin,

Thanks for your reply. Given below the details information for your necessary action.

1. I wish to receive local Medium Wave Band and Short Wave Band (A.M.Bands) with clear audioable and best selectivity and sensitivity from long distance Radio station specially at night.

2. My room space 10' x 10' available.

3. No I don't have pre-amplifiers or don't used for this.

4. Yes, my location is little bit noisy.

5. Yes, I have wood, PVC pipe 1/2" dia, and enamelled copper wire guage # 22,24 SWG.

6. Getting high gain output from weakest signals received.

7. As I told you before that I contruct a ' X ' loop antenna having single turns about 8 to ten turns of wire on a 2 wooden frame cut to 16" in length with 22 swg wire and attached a variable capacitor 365pf.

8. I used variable capacitor 365pf for tuning purpose, to get best results.But don't used any bypass filter to resonant to high pass or low pass bandwidth.

I hope that the above details will fulfill your requirement, and let me have your best suggestion soonest possible for which I thank you in advance.

Best Regards

Abdullah Bawaney

Dear Cor Beijerbergen,
I thankyou very much for the instant reply.
I have already visited those websites which you mentioned, and contruct various loop antennas, but unfortunately it does not work. Acctually I wish to construct those loop antennas which not need connection with the receiver, you only place the received inside the loop and it work good compared to selectivity and sencitivity.It is a great project for those who are very found of dxing. I have seen videos at youtube.com .
Kindly visit youtube, and check at your end. If you have an idea or suggestion please let me know.
Thanks again, and looking forward to the pleasure of hearing from you soon.

This small UNTUNED loop works just fine for AM 530-1700 khz. There is no tuning capacitor, just the wire. It measures 12" (305 mm) on the sides, and 17" (431 mm) across the diagonal.

http://socalradiowaves.com/columns/am_antenna.html

I've build several of these for my stereo systems' tuners.

I have also built this tuned loop.

http://www.mtmscientific.com/loop.html

If you click on "Photos and Review from Customers", the second antenna on that page is mine.

Specifications are: 17" (431 mm) on the sides, and 24" on the diagonal (607 mm). There are 15 turns of 22 ga "magnet wire" (or "enameled wire"), with a separate pickup loop just inside of the 15 turns. The 15 turns of wire are spaced 1/8" (3.2 mm) apart. The tuning capacitor is the common 10 - 365 pf.

I have also built a shortwave (HF) loop similar to this one:

http://www.mtmscientific.com/swloop.html

It used a single turn of wire and the same type of 10 - 365 pf tuning capacitor, the loop measuring 36" (914 mm) on each side.. This was rigged up from scraps of wood molding and parts in my shop after a hurricane, when my main SWL dipole had been blown down. Since we had no electricity, my receiver was operated from batteries, and to make the loop I simply twisted the wires together, no soldering.

I was able to hear everyone on a regional 75 meter net, from my home in Louisiana, to net participants in Texas, Mississippi, and Arkansas. And this was INSIDE of my metal shop building using an Icom R75 receiver.

I've experimented with loops using the same capacitor and various number of turns of wire using these online calculators by Bruce Carter.

9240. EZNEC+ model for 80 meter superloop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-08-26 17:20:14 UTC
From: Frederick Benson
Topic: 9240 Message: 9240

Does anyone have a functional EZNEC+ model of an 80 meter superloop antenna? See the diagram at the link below.

http://ars.nc4fb.org/80-meter-superloop/superloop-80-dimensions.jpg
<http://ars.nc4fb.org/80-meter-superloop/superloop-80-dimensions.jpg>

This antenna works as a Full Wave Loop on 80 Meters and also works as a 2 wavelength open loop or Bi-Square on the 40 Meter band. The 450 ohm ladder line stub acts as a switch on 40 meters to create the Bi-Square configuration.

If anyone has an EZNEC+ model of the antenna to share, please send me a copy as an Email attachment to nc4fb@....com.

Thanks,

F. Benson

9209 Power Supply Question

Hi Ralph,
for best S/N better do not use a mains power supply, for even with filtering some mains noise will be capacitively induced. This is true not only for the antenna, but also for the rx. Use batteries or NiMgH. Disconnect the charger from mains when operating. Juergen

No, but a number of net controls and assistant net controls of one of my favorite 75 meter nets use the Superloop 80 to good effect. They really like it.

Hello

I modeled this antenna using EZNEC and it works much better on 40-meters compared to 80-meters with the top section 60-feet high. The radiation pattern displayed for 40M was quite flat-topped (not much vertically being radiated but no null at 90-degrees) while on 80M it was radiating most of the power straight-up showing something like 6dB gain at 90-degrees.

I should have moved the wires up to maybe 80-feet and observed the gains on both bands but, then, most folks will have a hard time getting the top wires up to 60 feet so I didn't bother to make that evaluation.

9244. 160 meter delta loop.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-08-29 02:31:36 UTC
From: don.stefanik
Topic: 9244 Message: 9244

Hidee ho good neighbours.
Just joined the group and am planning on putting up a 160 meter loop antenna hopefully up 75 to 100 feet high.
My question is ...is it ok to have the antenna run over a couple of buildings with steel roofs? The one is 80X60 and the other is 40X50.
600 ohm ladder line going to a 4to1 balun.
Is there any reason why I shouldn,t run it over the buildings?

If this is not acceptible then I can run it shorter about 550'to 530' and in a delta configuration.
Thanks.

Welcome! I had an 80 meter loop up, in a square, with one leg about 20ft above a steel-roofed/steel-sided pole barn. The only problems I had was the deep nulls when I would tune it up on 20m. On 75m it was killer, and on 20m it had some lobes with lots of gain, but it had those deep nulls in between, too.

It will have effect, but on 160 I would not worry about it.
I would keep the feed point away fron the buildings, just for good measure.
However, keep in mind that on 160 the loop feedpoint impedance is around 25 Ohms at 10 meters high, and goes up with an additional height.

My experience with "nulls" at higher frequencies - the antenna automatically (!) "picks" the best propagation path for you!
I newer used it on 160, and it may be just a great cloud burner due to the height.

Jim,

You could replace your current antenna with something like this <http://www.carid.com/metra/item-1185428.html?CAWELAID=1498516837&> . It would make your embedded antenna useless, but it sounds like you already feel that way about it :)

It also looks like this one requires a hole drilled in your car...not sure you want to do that. There are mounts that could be found that would allow you to mount on a gap...like between your trunk and rear quarterpanel.

Dave

9249. Introduce myself and a short story about wideband loop matching (NIC based)

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-03 05:06:31 UTC
From: claudio
Topic: 9249 Message: 9249

Hi all,I'm IT9JCB, Claudio from Italy. I've just joined the group today because of my great interest on quiet receiving loop antennas.The man made noise has been always a problem for me, frustrating all time long for years. I'm also an old enginneer so I've decided to start an investigation about a suitable loop antenna able to reduce such a terrible noise.Starting with the commercial products the most attractive one at the moment seems to be the well known Wellbrook loop, manufactured in the UK by a Ham. I've heard good reviews about it but being an engineer I tried to better understand how this magic loop works, sent an email to Wellbrook got no results: secret project !
I think that we can split the small loop antennas into two main categories:
- tuned, and then "narrowband"- untuned or so called "wideband" as the Wellbrook one.
Leaving the tuned loops out for a moment, it seems that a wideband loop has severall advantages especially if you use the antenna over a wide range of frequencies and got tired to tune and tune the loop each time, furthemore a remote tuning circuit is needed plus a suitable tuning element in the loop.
Tuned loops have solid bases today, but first we have to remember that the effective lenght (He) of a small loop is only a little fraction of that of a whip with the same length, that means that we need to increase this figure by means of matching or/and amplifier. In the case of a tuned loop just adding a capacitor to form a resonator boosts up He to (Q*He) without noise issues being a totally passive matching, here we have the well celebrated tuned loop, Q could be eventually 200-300 so we did the job even without any amplifier. But ....we have to manage something like a 10KHz BW on the 40m ham band !!!
Now comes the magic "low noise" untuned loop. Untuned loops supply very low voltages in response to the incoming magnetic field, a loop of area A has an effective length of
He = 6.28*A/ lambda (lambda = wavelength)
so for example a 1 sq meter loop (1x1m) has
He = 6.28/40=0.157m on 40m ham band
To comparison, an half wave dipole has He=13m and a Q=100 tuned loop has 15.7m providing an active high impedance buffer to feed the 50Ohm load of the receiver, so....it seems that we need some magic preamplifier having nearly 0 dB noise figure.
The Wellbrook loop is for sure a well designed product and the designer has spent lot of energies and waste of time to do it, for sure, but I don't believe on magic.
Here enters the NIC, also known as Negative Impedance Converter. If we look to the small loop equivalent circuit we'll se a series of:
a voltage source V + resistor R (loss+radiation) + an inductor L

In the case of the tuned loop, the inductor L is cancelled by the tuning capacitor, so at resonance the loop current will be simply I=V/R (Q boost), its "ultimate" maximum value. In the case of the no tune one we have
I=V / |R+jXL|
that can be many orders of magnitude lower, especially at high frequencies and with practical loops (L can be lowered but would require an unrealistic conductor diameter).
The first attempt could be to close such untuned loop to a short circuit to maximize the current, a loop closed to a common base amplifier with enough rest current does the job but how much is the output SNR ? I've used spice to simulate many of these amps, the best results I got is for a BC550 20mA with inductive compensated load + voltage follower-buffer, it gaves me a remarkable 0.4nV/sqrt(Hz) input noise voltage in the 1-15 MHz band.In this case an incoming 1 uV/m electric field that produces on the half wave dipole (40m band) a 13uV input to a receiver (or a S5 signal), will induce on a 1 sqm loop only a miserable 0.157 uV !!
Assuming a 2500 Hz BW the out SNR of my amp is 157nV/(0.4*50 nV) --> 7.85 --> 18 dB which is not bad at all if we take into account that the man made noise floor can eventually be higher than the amp noise.
Can we do better ? Yes, if we had an ideal NIC.The ideal NIC is as follows: you put an inductor L on its output and it appears as a -L (minus L) inductor on its input, if we put this NIC in series to the loop it will cancel its inductive component at
"all frequencies"
This is something magic ! The final result would be that we get the Q-boost effect at all frequencies, with the relating SNR boost.But what really happens ? I've performed intensive spice simulations over a large number of transistors based NIC and the results can be summarized as follows:
The goods ones
- The Q-boost effect really exists- The loop works wideband as expected
The very bad one:
- The noise introduced by the positive feedback's nature of the NIC is so high that the resulting SNR is well below that of the simple common base amp described here before. Any attempt to reduce the NIC noise, even using ultra low noise LF transistors, has simply failed.
I wonder if the Wellbrook loop uses some form of NIC-like circuit with better noise figures, as said before I didn't receive any answer from the designer.
If anyone did some experiments with NIC or has some others useful infos about, please write.
73s IT9JCBClaudio
PS: simulations performed assuming a 1m dia loop made-up by 12mm dia conductor, inductance of the loop 3uH, frequency range 1-15 MHz.

I've experimented with numerous approaches to an NIC amplifier for active loop antenna applications, but have had no success to date. I have a couple of ideas that I have yet to try.

In the meantime, I did design a wideband amplifier for loop antennas that outperforms the Wellbrook and Pixel commercial products:

This is a very old idea. For example, see:

http://www.loe.ee.upatras.gr/MW/Papers/2009_APS_Non-Foster%20Circuits%20for%20Small%20Broadband%20Antennas.pdf

which cites a 1957 paper.

If this concept worked, you would be seeing it in extensive use. However, there is no magic, no free lunch. Negative resistors may have negative resistance, but the noise temperature is still positive. I did some simulations a few years ago and confirmed the bad news.

Thanks for your suggestion Dave. I looked at their website and it appears they have other types as well, including the following:

http://www.carid.com/metra/item-1185404.html

which might work well enough for me inside the car.

Jim

AM car reception often depends on the radio itself and not just the antenna. My 2004 Bonneville with a rear window antenna easily outperforms my 2005 Mustang with a fender mounted whip. Stations come in stronger and with less electrical noise in the Bonneville. Best car dx was KOA Denver and WOAI San Antonio into Mass. Jim

Hello, I'm from Singapore. My friend and I are doing a project on Lightning Observatory in our school campus and we are considering using Loop Antennas to obtain our results since they are both VLF. We are completely clueless about these stuff and could only help ourselves with the information on the internet (hence do bear with me with the terminologies...). We were wondering if you guys have any tips to give us to built the loop antennas and also if loop antennas can record up to 180º or 360º (signal wise). Thanks!

If there is any other information you need to know, do ask :)

Hi Rick,
I know that is a very old idea (I guess dated in the 50's) as well as the first NIC introduced by Linvill, what sounds strange to me is that with the today's semiconductors the noise introduced by the NIC is still so high. To be honest I didn't preform any special analysis on this, simply observing the simulation results.
Your statement is correct, a negative resistor -R has same noise voltage -kTR as the positive one, but here we have a boost in noise which has no explanations for me up to now. A detailed noise analysis is strongly required.
To be continued....

Unless you're wanting to be able to "Null" a signal, I would highly recommend that you use an active "Whip" antenna for your project. Many (most) are wideband, will work well down into the VLF range, be non-directional and most likely outperform any but the largest loops.

I've built and used many of them using various circuits (google the web for "Active Whip Antenna"), AND in fact am using one here for my Primary DXing hobby of chasing NDB's (longwave Non-Directional Beacons). Used them for MANY years.

9257. Question About Homebrew Shortwave Magnetic Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-03 23:24:25 UTC
From: Nick
Topic: 9257 Message: 9257

Hi All,
My name is Nick, and I live in central North Carolina. I have been a radio listener for over 40 years, and have used loops for the broadcast band...but never for shortwave. So, I decided to try it just to see how it turned out. I looked up all of the parts that I needed from my "junk box", and more or less threw together a prototype to just test it out. I was quite impressed with the performance, but not happy with the construction. It was held together with garbage bag ties and zip ties. I decided to dismantle it and build it more sturdy. I also decided rather than using the old parts, that I would go with all new parts. So...my question is, I have a new 2 gang 350 pf capacitor which I thought about enclosing in a metal (aluminum) project box for mounting on the antenna mast (PVC pipe). If I bolt the capacitor to the metal box, would I not effectively be putting the metal of the box in series with the rotor blades and frame of the capacitor? Would this not affect the tuning range of the whole antenna? Has anyone on the list here tried this before?, and if so, what were the results? Hope someone can help with this one?

Thanks for any help,
Nick Rumple

Hi Chris,
good news, I'll be brief now but I'll give a more detailed report later on. I added the augmenting circuit to my amp (you find it in the file section as "IT9JCB's...etc") using an ideal VCVS as tranformer to simplify the job. The ratio used is 5 (best one).
These are the interesting results:

W/O AUG:
emitter imput impedance ~1.2 Ohm, freq. dependent
Gain 30 dB in 1-15MHz
noise voltage rti 0.47 nV/sqrt(Hz)

W AUG
(I'd to increase the input transformer ratio from 3:1 to 5:1 to better match the new low impedance)

emitter imput impedance ~0.3 Ohm, freq. flat
Gain 42 dB in 1-18MHz
noise voltage rti 0.25 nV/sqrt(Hz)

In few words we gained about 6 dB in SNR, furthermore it seems that the impedance seen by the loop is now much resistive and flat on frequency.

Is this the Andy's secret ?
Anyway, could you provide me more info about your results with NIC and some schematic, if possible, thanks in advance.

Claudio, one of your files has no extension. Could you correct that please?

And could you crop and reupload the JPG? It is rather large and takes up way more space in the Files than necessary. We only have 18% space left out of 100MB.

Thanks,
Steve Greenfield AE7HD

My teacher wants us to construct the antenna ourselves and not buy an antenna as it will be the "engineering" part in the report we would have to write later on. He suggested us to research on circular antennas but its a VHF so I don't think it would work. Do you have suggestions on what other possible kind of antennas we could use?

> If I bolt the capacitor to the metal box, would I not effectively be putting the
> metal of the box in series with the rotor blades and frame of the capacitor?

Maybe not really "in series" but maybe "in parallel".

But the box isn't really a 2-terminal element. It's more of a big
hunk of metal, bent into a shield.

> Would this not affect the tuning range of the whole antenna?

Could, depending mainly on its proximity to, and coupling to, the loop
itself. And to some degree, if the box couples to the capacitor
blades inside the box.

You could always try using a plastic box instead of metal.

Back when I used to fool around with old radios, some of those 365 uF
capacitors were, I think, insulated from their mounting screws. (Or
maybe I am just remembering this wrong.)

I don't know if your loop (and the circuit it connects to) tries to
maintain any sort of electrical balance, but a box connected to one
end of the loop probably upsets the loop's balance.

Andy

9264. Re: Car reception question

I hope you and others on this list won't find this post offensive, but here is an approach that - depending on your priorities - you may want to consider.

Let me begin by saying that I too am a lover of good AM repletion while in the car, to the extent that I've let it influence what car I bought. But, like it or not, times are changing. Some factors that make it more difficult than in the past are: As you point out, car radio antennas are no longer performance oriented. Cosmetics are more important. The same can be said for the in-car receiver itself. As more and more AM transmitters are loading up their sidebands with extra services, the adjacent channel interference wipes out many stations. The addition of more and more in-car electronics, including several processors and computers creates a much noisier RF environment. Modification of the antenna, possibly the head unit and addition of filtering are often required to obtain only mediocre reception.

OK, time for the blasphemy - Use streaming audio from the hundreds (probably including the ones you want) of AM stations offering it. I stopped fighting with conventional reception a year or so ago and am happy I did. On long distance trips I just connect the audio from my iPad into the car's audio in jack. Free applications such as IHeartRadio, TuneinRadio, RadioBox and NPR easily provide one-touch selection of dozens of your favorite stations from all over the country (and beyond). Streaming audio isn't data intensive. I have the $20 a month Verizon 1 GB data plan on my iPad and only use a very small fraction of it for streaming radio stations.

Of course this all depends on your motivation for wanting better AM reception. You might be looking for the satisfaction of solving an interesting engineering challenge. I can totally understand that - I've been there for many decades myself. On the other hand, if your main objective is obtaining the content of the AM stations with high listenability while in the car, the streaming audio solution is the way to go. Essentially hassle free compared with the other alternatives.

By the way, this advice applies equally well to AM reception in many of today's homes. With the EMC environment of all the computers, smart appliances and close neighbors with the same, its a similar problem as in a car unless you have the space to install an outside antenna that is 50 ft or more away from any houses.

In the late 90's Nuts and Volts had a project to build a lightning storm tracker displaying results on an Oscope. They used loop antennas fabricated from ribbon cable the best I can remember.

Hi Stacey,
one of the best website dealing with vlf is : "Radio Waves below 22kHz"

    http://www.vlf.it/

As far as I remember, there is a lot about lightning detection on the web.
Look also for sprites and elves ! Highly interesting, because still of unknown origin.

Regards from germany ! Juergen

Hi Stacey,
one of the best websites I have ever seen covering your subject, is : Radio Waves below 22 kHz, url :http://www.vlf.it/

Very, very good ! Look also for "sprites" and "elves", highly interesting, because of unknown origin.

There is a lot on the web about lightning, but first try the one above.
Regards from Germany ! Juergen

The problem with this typw of aerial is the short length; while it
is (probably) helical construction, a longer single whip would be
more efficient. While less common, they are available (My Honda
has one).

> It also looks like this one requires a hole drilled in your car...not

If the OP doesn't want to drill his car (perhaps there's a
blanking plug somewhere that would be used for a standard aerial
on other models), alternatives are a gutter mount (if he has
gutters) or at a pinch a magmount. All these need trailing cables
though.

My reccommendation would be to ask the local car service shop to
install a body-mounted aerial.

Hi Steve,
I've compressed the files and now they are all JPEG.
Note that these are simply spice simulation files, real circuits will appear different, moreover a balanced push-pull configuration will be used to reduce 3th order IMD. As said before to folk these are preliminary experiments to design an build a wideband no tune loop antenna for SW reception having extremely low noise, any attempt to use NIC to match and boooost the gain are failed up to now, but I'm continuing on work. Liked your interest on this topic.

Hi Andy...
Thanks for taking the time to answer my question, and also for your input on the situation. I finally decided that the only way to really find out for sure was to try it out both ways (with and without the box). To make a long story short, I built it and tried it out both ways today, and saw virtually no difference at all. Whatever the case really is, It does work really well and I am happy with it, so I am going to leave it the way it is....for now. :)

Craig, I forgive you, especially since you were so polite and knowledgeable! You make some good points, at the cost of some money up front. Streaming audio is inevitable, but I guess I am going to hold out for now, preferring to divide my car time between books/educational material on CD, tape (still), Ipod and so on, and some listening to the radio for variety.

--- In loopantennas@yahoogroups.com, Craig Smith <craig@...> wrote:
>
> I hope you and others on this list won't find this post offensive, but here is an approach that - depending on your priorities - you may want to consider.
>
> Let me begin by saying that I too am a lover of good AM repletion while in the car, to the extent that I've let it influence what car I bought. But, like it or not, times are changing. Some factors that make it more difficult than in the past are: As you point out, car radio antennas are no longer performance oriented. Cosmetics are more important. The same can be said for the in-car receiver itself. As more and more AM transmitters are loading up their sidebands with extra services, the adjacent channel interference wipes out many stations. The addition of more and more in-car electronics, including several processors and computers creates a much noisier RF environment. Modification of the antenna, possibly the head unit and addition of filtering are often required to obtain only mediocre reception.
>
> OK, time for the blasphemy - Use streaming audio from the hundreds (probably including the ones you want) of AM stations offering it. I stopped fighting with conventional reception a year or so ago and am happy I did. On long distance trips I just connect the audio from my iPad into the car's audio in jack. Free applications such as IHeartRadio, TuneinRadio, RadioBox and NPR easily provide one-touch selection of dozens of your favorite stations from all over the country (and beyond). Streaming audio isn't data intensive. I have the $20 a month Verizon 1 GB data plan on my iPad and only use a very small fraction of it for streaming radio stations.
>
> Of course this all depends on your motivation for wanting better AM reception. You might be looking for the satisfaction of solving an interesting engineering challenge. I can totally understand that - I've been there for many decades myself. On the other hand, if your main objective is obtaining the content of the AM stations with high listenability while in the car, the streaming audio solution is the way to go. Essentially hassle free compared with the other alternatives.
>
> By the way, this advice applies equally well to AM reception in many of today's homes. With the EMC environment of all the computers, smart appliances and close neighbors with the same, its a similar problem as in a car unless you have the space to install an outside antenna that is 50 ft or more away from any houses.

Yes, they are impressive, agree. I'll continue now by using a true transformer for augmenting, it is a 1:5 and a low out inductance is required to fed the TR base, so I will work about it and then add the buffer. Finally a balanced push-pull version is required to reduce the 3th order IMD issue but i leave this to end.In the while I realized that reducing the loop inductance can give further improvement (the NIC job would be this one), so I'm investigating to a new loop geometry (not a simple big conductor diameter) able to reduce this inductance in some practical and inexpensive way. The basic idea is to use a planar structure covered by a large copper foil. I'll keep you informed about the progress of my work, my spare time is limited too.Back to Andy, assuming not augmenting, he states in the brochure that some form of "impedance tracking" is used, automatically recall the NIC...Anyway you

can test online the performance of its loop connecting to the web site www.websdr.com and choosing a station in NL which uses its loop, open in a different window another station page (Maxwell etc) located very close to it, it uses a full-size dipole, and so you can compare the two antennas using the same station.I did it some time on 40m band....but i left you discover yourself, if interested.
Thanks for good help.

I've found this interesting document about AL-1530S+ Wellbrook:

http://www.nakatoyo.com/wellbrook/ALA1530S_PLUS/ALA1530S_c_4.pdf

The words "negative impedance" and "non-foster matching" are evident.
Strangely, this doc is not present in the wellbrook site, that means that or have been removed or it's not still a valid doc.

Hello Claudio,
You can visit
http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.\
htm
<http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna\
.htm> . The paper treats similar problems and might be of some help to
you. I have some remarks about active wideband loop antenna:

1. It is better to use Norton equivalent circuit for the small loop in
the spice models. The current source becomes frequency independent and
this corresponds to the physical nature - small loop loaded with
resistance much smaller than its inductive impedance gives fixed current
(short circuit current) irrespective of the frequency.

2. The wideband loop amplifier is current to voltage converter. I will
suggest giving its gain as a ratio of output voltage to input current.
Gain= Uout/Iinp [ohms]. Dimension is ohms and I called this
trans-resistive gain. The amplifier presented in my paper has a gain of
approx. 650 ohms (1uA @ input will give 650uV @output). It is now easy
to compare different loop amplifiers gain irrespective of their input
resistance. It is straightforward to obtain the output noise voltage
and trans-resistive gain in spice models.

3. It is also convenient to compare their noise floor expressed in
uV/m. Dividing the Uout-noise/TR-Gain we will easily obtain the input
noise current and compare it to the loop current by applying the simple
and quite accurate equation for the loop short circuit current from the
field intensity. So we can easily obtain (or compute) the noise floor of
an amplifier with a specific loop expressed in uV/m. This is the most
important parameter of the wideband loop and it is pity that it is
usually not given in the loop specifications (except for some commercial
professional cases).

I am giving these suggestions since if we try to compare different
amplifiers and antennas we should have common terms. For example I can
not evaluate any active loop if its noise floor (in uV/m) is not given.
Evaluating and compareing different loops with on the air tests by
saitsfied customers is not very accepatble for me.

4. The noise figures which you obtain in spice models are of the same
order as in my models. I can say that in the flat frequency region the
experimental results are very close to the spice models. My experiments
with common base (CB) amplifiers show that usually the loop sensitivity
is limited by the internal noise (not by the atmospheric) for
frequencies above 10 MHz. In practice, 1 m diam. active wideband loop

with L<=3 uH, with simple CB amplifier,below 10MHz, at night times has an acceptable noise floor which is below the atmospheric noise level even in rural places. In order to obtain better reception during daytimes and higher frequencies we need some 3 - 10 dB lower active antenna noise floor. This sensitivity can be reached more easily with small active whip (electric) antenna (see Fig.1.6 in http://www.active-antenna.eu/tech-docs/1_ActiveAA_DandS_20.pdf). So the fight for every dB noise reduction in CB active loop amplifiers is very important.

5. I have not tested the augmented amplifiers (suggested by Chris Trask) and your noise floor results with them are quite interesting.

6. I am skeptic about the possibility to reduce substantially the active wideband loop noise floor. The reason for that lies in the very small current of the loop. Probaly there are physical limits ☐ I will give a very approximate example: In 1 m diam. loop with inductance of 2.4 uH,the induced short circuit current from 1uV/m external field in the flat frequency response region will be 1.1 nA. To simplify the case let's assumethat the loop is loaded with 3 ohms resistor which emulates the input resistance of the differential CB amplifier. The voltage drop across 3 ohmsload resistor will be 3.3 nV. From the other hand the thermal noise voltage at290 deg. K of 3 ohm resistor at BW of 1 KHz is 7 nV. In this case we have 2.1 uV/m equivalent noise floor @ 1KHz BW of the loop which is terminated with 3 ohms load resistor - from my point of view this is the main factor that limits the noise floor of a wideband loop terminated with low input impedance amplifier.

7. The most effective way to reduce the loop inductance (and noise floor) is with Crossed Parallel loops - see my paper.With large crossed loops the noise floor can be reduced substantially and it is possible to have antenna limited by the atmospheric noise.

8. I do not have experience with NIC - they are promising because they probably aviod the above mentioned limitations, but we should consider also the non-linear behavior of these circuits.

9. The balanced scheme improves IP2 not IP3 (probably you have made a lapsus).

Wish you a success in your project and I will be glad if you publish your results.

Chavdar, LZ1AQ lz1aq@... <mailto:lz1aq@abv.bg> , www.lz1aq.signacor.com <http://www.lz1aq.signacor.com/>

P.S. I will be on my holiday the next 7 days at a place where there are no telephones and Internet :-) so I will answer any possible messages when I am back.

here it is:

assume that in some way we are able to reduce the CB amp impedance to just...say 0.3 Ohms, the thermal noise voltage will reduce about 20 dB, but we must include in these simple analysis the noise current of the amp itself.
Anyway reducing the input impedance to sub-ohms values gives the advantage, now we have to understand how to do this without increase the noise (not simply increasing the TR Ic !!), one way is the Chris Trask's patented technique, but I found that it works as adviced only using ideal VCVS, a transformer gave little improvement, just yesterday I tried with an active solution and the initial results are encouraging.
The other two advantages of this augmented circuits are:

1. being Rin so low, it acts as short to ground, so even umbalanced loops can be used with lees sensitivity to electric fields.
2. the augmengting tecnique has some effect of linearization on the input impedance, being Rs linear the ratio RL/Rs is more linear too.
I observed about 7-10 dB of improvement in 3th order products.

9288. Coaxial Relay

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-13 18:04:26 UTC
From: drewbhoy67
Topic: 9288 Message: 9288

Can anyone recommend a coaxial relay to use with my wellbrook 1530 as my transceiver doesn't have a receive only input.

From: Rich
Topic: 9289 Message: 9289

I may have missed this one as I posted on a few sites.
Rat Shack has an AM loop ant. on clearance.
It's an Eton E200 for $14.97,tried mine and it works fine.

9290. Low noise loop Amplifier: final report

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-15 06:30:32 UTC
From: claudio
Topic: 9290 Message: 9290

Hi all,
I've completed the design of my low noise loop amplifier and the results are available in the pdf document "loopamp ver1_1" located in my folder named IT9JCB, so anyone interested can give a look a send back comments.
The final results as remarkable, the input noise voltage rti is less than 500pV/sqrt(Hz), all details as well as the measurements plots are shown in the pdf.
The amplifier uses very common and inexpensive components as the well known 2N2222A transistor, the only critical component is the 3:1 input current balun, it can be built using a four wires winding in a suitable generous size toroid.
In the while a new NIC based version is in progress and the first results are promising, a related report is coming soon.

I would like to play around with some variations of this
circuit. Would you be willing to zip everything together,
that I would need to run your simulation in LTspice and
place it in the same folder?

For instance, I want to see what difference (if any) it
would make to inject the input stage bias current into the
balun, instead of directly into the emitter. That would
take the stray capacitance of the large input coupling
capacitor out of the response and bypass the noise of the
bias resistor (and any bias supply noise, that will always
be worse than the the perfect voltage source in the simulation).

Thank you.

9293. The "Beacon Audio Archive"

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-15 18:16:38 UTC
From: Phil
Topic: 9293 Message: 9293

Hi,
First, I hope that the moderators of this list doesn't find this post too far "off topic", but many loop antenna owners do use their loops for DXing NDBs (Longwave Non-directional beacons). Right now I'm primarily using an active whip for the purpose, but have a tuned loop in the process of being built especially for NDB's. My primary beacon receiver is an Icom R-75 with cascaded 250Hz narrow CW filters installed and is set up especially for this purpose.

A little over two weeks ago I started a new Blog site, I call it "KO6BB's Radio-Beacon Audio Archive". The premise is simple, to post recordings of as many NDB's (and eventually other beacons) as possible. This because every year many of them are being shut down as Airports no longer deem them necessary. I foresee the day when the NDB DXer will no longer be able to follow his chosen hobby. . .

It's also a place where one can compare what they may have heard against a recording of the actual beacon on the air, though it must be remembered that beacons sometimes change formats, OR have problems with their keyers that cause anomalies in their signal.

Some of the recordings on my site were recorded by other DXers, all of the pictures (what there are) were provided by others. ALL material provided by others are given due credit in the postings.

MOST of my own recordings are very narrow bandwidth, having been recorded using the Icom R-75 with 250 Hz CW filters AND very narrow audio filtering using the Timewave DSP-599zx. This because of the high noise levels encountered at LF. There ARE a few recordings of stronger (local) beacons using the AM mode and no audio filtering to show what these sound like in the AM mode (the beacons all use one form another of AM modulation). Where the AM mode is used, there is also a second recording in the narrower CW mode.

SOME of the recordings are very noisy, that goes with the hobby. But ALL of them do have the ID fully readable, I don't DON'T post recordings where one has to guess at the ID.

As of today there are recordings of 131 different beacons, EACH with it's own descriptive Blog page containing the recordings, pictures (where available), and other information such as frequency, location etc. New beacons are added almost daily.

To get there got to my home page at Ipernity
http://www.ipernity.com/home/ko6bb
then click on "blog" right next to the little HF radio symbol, or this will take you directly there if you wish to bypass my home page. . .

Hi John,
thank you for interest in my work, yes I can do it if you wish, will zip all my docs into a single zip file.
Anyway I liked your idea to supply the TR via the bottom side of input transformer but a large bypass capacitor is also needed to short the bias resistor, so the big cap issue remains.

The 220 Ohm bias resistor in the emitter does noise but it is shorted by the TR input impedance which is in the order of 2 Ohms, anyway will try myself as well to see if it makes some difference.

In this version, both ends of the cap ride on the signal voltage (which is pretty low, because of the low impedances), but it is still a route for external capacitive currents to enter the emitter. When the capacitor is moved to the other side of the balun winding, as a bypass cap, one end is tied to ground, so almost all to the stray capacitive current would go directly to ground, not to the emitter.

You could simulate this difference by making the stray capacitance to each end of the capacitor explicit, and connect them to some AC voltage source representing an interfering signal. Admittedly, this external interference could be kept arbitrarily low, with shielding, but this stray capacitance also represents a sneak feedback path from all the nodes that have amplified copies of the input signal, that might distort the frequency response.

So, if it costs nothing to reduce this stray path (by reducing the total stray capacitance to the emitter node), it might be worth at least the cost to do it.

Hi Chris,
thanks...being an old IC silicon designer I'm used with current generator biasing, you know. This is the best way to bias an high power linear amplifier.
I tried to add augmenting to this design, but honestly the only improvement I noticed is in the input impedance drop and few dB less of IMD3, tried to best match changing the input transformer ratio leads to same results, noise is the same or worst.
I'm very interested on your NIC work, I'm working on mine, it seems to work decently but the results are a little be worst in terms of noise, still working. I got the Linvill original papers and read it carefully.

9300. Re: Question About Homebrew Shortwave Magnetic Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-17 16:18:33 UTC
From: Nick
Topic: 9257 Message: 9300

Hi...
Thanks to everyone for the help and advice that you offered. it was much help. I went ahead and built it in the metal box, and it really works great. I also have a 220 foot inverted L longwire, running NE to SW about 45 feet high, and the loop will receive anything that the longwire will, and some that would be completely under the noise on the wire. I don't know what the Q of the loop is, but it must be huge....It is so sharp, that I had to add a 3.5:1 drive reduction unit to the capacitor to be able to tune it on the high end. The loop coverage starts, on the high end, at about 15 mHz. (with 1 gang capacitor), and tunes down to about 3.2 mHz. (with 2 gang capacitor). I do wish that it would go a little higher, and cover the 19 meter shortwave band, but I can live with it like it is.
So thanks again for the help, and good listening to everyone.

Nick

9301. Building a LF loop using multi conductor cable with shield

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-19 04:41:40 UTC
From: chuckmfspd
Topic: 9301 Message: 9301

I have read of loops built by connecting the ends of the wire in series to make a large multi turn loop. My question is about the shield
all the multi wire cables I have seen all have a shield, would this type cable still be ok for LF 150-550khz ?

Chuck,

I've seen probably one of the tutorials you are talking about. You want to look for unshielded cable. It's okay if there is a plastic insulator on the outside, but what you don't want one that has a woven or film metal shielding layer.

Lowes or Home Depot carry unshielded multi-strand cable you can buy by the foot. You'd probably best to try to find some that isn't twisted. I think they offer unshielded thermostat wire that has multiple conductors and are unshielded.

Dave

Another way is to buy ribbon cable. There are many sources including iPAY(Ebay). Decide how long the loop/big should be & how wide, then solder the two ends together, but offset the ribbon by one wire. This will create the "spiral" and leave 2 unconnected wires for installation of a variable cap and or connection to the radio. You can also tap off this loop at various points for various tuning flexibility. - 73 Bob V

Hi Chuck,
ribbon cable will function satisfactorily, but remember the small diameter and the tinned surface of the wire, which result in relative low Q of the tuned antenna.
Juergen

Hi Chuck,
the cable MUST be unshielded, in case of shielded loops the shield must be broken in the mid of the loop, this cannot be done with multi turns loops.
Here in Europe there is a wide choice od unshielded cables, as in the US I guess. Don't use too thiny wires, at least 1mm2.
Here is an example of 18x1mm2 cable, 18 wires, it costs about 5$ per meter...not too cheap.

9307. First NIC based loop amplifier that seems to work

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-09-20 03:21:10 UTC
From: claudio
Topic: 9307 Message: 9307

Hi all,
I've continued to work on NIC (negative impedance converter) based amplifiers for small loops antennas.
As well known a small loop has an impedance of the form : R +jXL, where R is a small resistance (say less than 1 Ohm) and XL is the inductive component, such a component can be of the order of many hundreds of Ohms at high frequencies and it's the main limiting factor of the loop's current value, a resonant loop maximizes the current cancelling XL with a capacitor XC, so at resonance I=Vi/R where Vi is the (small) voltage induced in the loop, but being R very small the current induced in a small resonant loop can be very high, if an high Q is provided.
So the main task of any aperiodic loop amplifier is to maximize the current being XL the limiting factor. Up to now the best way has been to close the loop into a very low impedance amplifier whit low noise (see my low noise amplifier in my IT9JCB folder), the natural -6dB/oct roll-off due to XL can be compensated (if needed) by using an inductive "tracking" load.
If an ideal NIC was available the natural way to follow would be to close the loop into a a "-L" NIC being the other side of the the NIC closed into proper load or better, a low impedance amp. This arrangement insures a flat response and max current, i.e. a perfect match to the loop.
Unfortunately an ideal NIC is well far away from real world, resulting in very high noise e low linearity.
I tried to partially solve these problems, my NIC works as expected with reasonable performances in terms of noise and IMD.
A complete description of the NIC based amplifier can be found in my IT9JCB folder, the amp has little bit worst noise performances of my non-NIC amp, but I think that this is a good starting point for anyone interested on this important topic.
Today many research institutes in the world are working on NIC, the new big wireless market, 4G an beyond, calls for extremely wideband and miniaturized antennas and the NIC is the natural solution.

The major disadvantage of all shielded multi-wire cables is the high capacity between the wires and between wires and shield, which results in decreased tuning range.
The better way is to use only a few turns unshielded and couple to the tuned circuit via a transformer winding on the coil.
Juergen

Juergen

P.S.:
The shield of a multi-wire shielded cable can easily be interrupted by carefully opening the insulation and cutting the shield foil.

Just try a few variations of construction and learn by experience.
Juergen

Thanks, I found a 18' length of communication interconnect cable with about 16 small wires. I guess I will solder it up and try to pickup
some European AM broadcast on longwave tonight. Here on the east coast It sometimes drifts in during fall and winter.

I'd be careful of using that. Sounds like twisted pair cable. If used in the differential mode (twisted pair) it can help reduce the reception of electrical noise. Otherwise it is a straight piece of wire with about 29pF/foot (.3 meter) between twists and i can't recall some type of capacitance between other pairs of wires.

Your NIC gave me reason to reexamine the work I had done earlier, and I found that I had made a couple of conceptual errors. I just uploaded the result of that, showing a single-sided and balanced version of the NIC that I have devised.

Basically, the issue of noise is addressed by eliminating all resistors in the topology. I do this by using wideband transformers. One of the conceptual errors that I made in the past was combining the two transformers of the single-ended design into a single 1:1:1:1 transformer. Using a pair of 1:1 transformers seems to have taken care of the instability problem, according to PSpice.

Chris

Hi Chris,
thank you for giving a look to my work, it's a spare time job so don't expect great results..!
Yes, agree with resistors issues, if possible use chokes or transformers, or ...the lowest resistor you can use, especially for polarization, the TR's base is the most sensitive point.
I had'nt time to complete my doc, but i'll work on it this weekend, figures about noise and IMD are included, they are really not too bad at all.

I realized that it's not possible to fully compensate the inductive component on a low loss loop, the required current would be out the NIC range, so you have the leave a little L and add some R to make the circuit physically realizable according to the GBW of the available components, moreover the little R comp helps on linearizing the NIC and add some stability margin, I've used the floating version from the original work of Linvill and it's "conditionally stable" only, a full L compensation is not possible and be care with negative resistor as well.
I tried some microwave transistor to increase the GBW (the ones I'm used to work by), but noise performances are poor.
Will give a look to your work, would be great to join our efforts.
As soon as possible I would like to built my coax made indoor loop, I've big noise issues here on 40 and 80m in nightime.

Chris,
do you have already some results of your NIC ?? I looked at the diagrams, it seems very interesting. I liked the way you used the transformers and the resistor-less implementation. I expect good noise performances, would like to do some simulations myself, but unfortunately you don't specified the transformers ratios.

Thanks

From: Memwl
Topic: 9324 Message: 9324

Sorry to sound so dumb on wire strength but this question concerns a little of both
I want to put up an 80 meter loop, using 18 GA speaker wire supported by pvc rope/cord
I have a rectangular shaped yard that is 50 wide x 100 length so I barley have the room (I will use a tuner),
however the back has electrical lines along the back side, this is only on the back,
how far would I have to be to keep the noise down is it 20 ft or more, I had planned on using metal poles with fiberglass extensions to hold the wire, another question is how long to make the fiberglass pole
from the metal support pole, I am only using low power 100 watts

My problem is I have a overload of information, and have had my fill of trial and error, I know thats part of ham radio
but I am getting old and cannot keep climbing those darn ladders

I need suggestions

Claudio,

Just a thought; if you are conserned about possible resistor noise in your NIC you could replace R1, R2, R3 and R4 with 2.2mH chokes, you may need to reduce the +ve potential too. Likewise you could use the same value chokes to decouple the emitters. Adittionally you could connect the -ve side of the chokes to a balance pot. One other thing; as it is not possible to acheve perfect negative inductor, the resultant Loop/NIC impedance will not be zero, so it make be worth trying out using a higher input impedance amplifier. This may or may not help with NIC stabilty.

Good luck

Andrew Ikin

Andy,
I've added two files to my IT9JCB folder, as Chris Trask suggested I modified the NIC to a resistor-less version with more realistic power supply. Simply...I've found no difference, noise and BW are the same, IMD improved just a little bit.
To better show where noise is generated I added a noise analysis where the contributions of the different comps are shown, 1st the NIC TRs, 2nd The two 10 resistors in the emitters, others negligibles.
Unfortunately the two resistors in the emitters cannot be removed, if you do this you get a terrific IMD and lower BW, even if gain and loop current goes up.
We need some form of lossless feedback to replace the noises emitter's resitors, I'm working on it.
Note also that my first scheme is just a spice file, it will be rearranged with more realistic power supply and polarization.
Anyway the idea to use RF choke instead is good, but it's not strictly required.
Will try also to replace the CBA with an high impedance amp, I had in my mind the loop current maximization only so I placed a virtual short after the NIC.

Thanks and 73s
Claudio IT9JCB

I dug deeply into my files on negative impedance converters and active negative reactances and came up with a few useful ones. Two show how to linearize the Linvill NIC, but it's only useful for generating negative resistances as nonlinear voltages are seen by the reference impedance.

Another paper on a CMOS NIC was much more interesting as it uses fewer parts and the reference impedance appears to see a linear voltage and current. I modeled a version of

this using bipolar devices and transformers with PSpice to see how well it would work, and it looks promising.

I uploaded a short paper into the files section a few minutes ago that describes these. Just a little more food for thought.

Chris

Claudio,

You could try using 2 x parallel connected transistors each with 10 Ohm Emitter degeneration with then re-biased so each transistor draws the same current as with the 2 transistor design. This should lower the IMD.

Assuming that you get it working, I would suggest that you connect NIC to and Vector Impedance Analyser to make that you have a negative inductor over the antennas design bandwidth. This will also check if you have any phase shift issues due the coupling transformers i.e. to many or too few turns or the wrong core material!

Hello Chris,

Thanks for your two recent papers ref. NIC. Yestereve, I tried out FIG 5 "Realizable Form of the Bipolar Negative Impedance Converter" using 2 x 2N4401s in liue of 2N2222, T1 and T2 are 8 turns Bifilar on 2873000302 cores and R1 300 to 2k. L1 is a 4.7uH Siemems choke.

I just can't get it work. The first problem was that Q2 is robbing current from Q1 i.e. the transistors are not matched. To overcome this problem I connected the ground end of the T2 and L1 to a 100 Ohm pot. (wiper to ground and other sides decoupled with 0.1uFcaps). This allowed me to balance Q1 and Q2.

I have re-checked the circuit several times and varied R1. I am just not seeing a negative 4.7uH on my Array Solutions Impedance analyser.

Any ideas?

if you can get 4 transistors in there instead of Andy's two (do same as Andy on biasing and equalization) you should theoretically have a chance to lower noise (produced by single bipolar) by a factor of 2

best wishes Claudio

Check the phase connections of T1. If you have it backwards, then you won't see a negative inductor.

Andy,
nice to see you at work ! In my spare time I would try to simulate that scheme (Realizable Form of the Bipolar Negative Impedance Converter), but i'll do it tonight, may be....(I work all day long).
In the while I tried to follow your suggestion about the load of my NIC amplifier. I loaded it with a fet based amp changing the resistance between the Gate and GND. Above about 30 Ohm the circuit begins to oscillate (I suspected it), so it seems that this kind of NIC requires a low impedance load.
I've fixed Zin to 25 Ohm to see if something was improved, but i got worst results of noise.
So, the natural way to close my NIC is as: loop-NIC and SHORT, as in the case of resonant loop, I think that the resonant loop must be our reference model, i.e. maximize the loop current and probe just a bit of it to rig..
Will check the Chris's scheme as well, and advice you in case of news.

Andy,
you say like this: two TRs in parallel (but they could be 3,4 etc etc..) is like to have a single one with N times transconductance (gm) and N times lower Re degeneration ?
Interesting, for sure gm is N times larger (I've used it with FETs), let see if the total noise and IMD is better or worst.
About transformers I'm really a bit afraid about phase shift (I generally don't like transformers ..), but as I said you I did'nt see any improvement with Chris's scheme, so I think will left the resistors as in my original scheme and use only a single 1:1 current balun for balancing.

if you can get 4 transistors in there instead of Andy's two (do same as Andy on biasing and equalization) you should theoretically have a chance to lower noise (produced by single bipolar) by a factor of 2

best wishes Claudio
Paul

"Andy,
I've added two files to my IT9JCB folder, as Chris Trask suggested I modified the NIC to a resistor-less version with more realistic power supply. Simply...I've found no difference, noise and BW are the same, IMD improved just a little bit.
To better show where noise is generated I added a noise analysis where the contributions of the different comps are shown, 1st the NIC TRs, 2nd The two 10 resistors in the emitters, others negligibles.
Unfortunately the two resistors in the emitters cannot be removed, if you do this you get a terrific IMD and lower BW, even if gain and loop current goes up.
We need some form of lossless feedback to replace the noises emitter's resitors, I'm working on it.
Note also that my first scheme is just a spice file, it will be rearranged with more realistic power supply and polarization.
Anyway the idea to use RF choke instead is good, but it's not strictly required.
Will try also to replace the CBA with an high impedance amp, I had in my mind the loop current maximization only so I placed a virtual short after the NIC.

Thanks and 73s
Claudio IT9JCB"

Claudio,

You could try using 2 x parallel connected transistors each with 10 Ohm Emitter degeneration with then re-biased so each transistor draws the same current as with the 2 transistor design. This should lower the IMD.

Assuming that you get it working, I would suggest that you connect NIC to and Vector Impedance Analyser to make that you have a negative inductor over the antennas design bandwidth. This will also check if you have any phase shift issues due the coupling transformers i.e. to many or too few turns or the wrong core material!

I looked at this on PSpice earlier. Using a Wilson current mirror decreases the usable bandwidth slightly. The third transistor will also add noise to the circuit.

"Andy,
nice to see you at work ! In my spare time I would try to simulate that scheme (Realizable Form of the Bipolar Negative Impedance Converter), but i'll do it tonight, may be....(I work all day long).
In the while I tried to follow your suggestion about the load of my NIC amplifier. I loaded it with a fet based amp changing the resistance between the Gate and GND. Above about 30 Ohm the circuit begins to oscillate (I suspected it), so it seems that this kind of NIC requires a low impedance load.
I've fixed Zin to 25 Ohm to see if something was improved, but i got worst results of noise.
So, the natural way to close my NIC is as: loop-NIC and SHORT, as in the case of resonant loop, I think that the resonant loop must be our reference model, i.e. maximize the loop current and probe just a bit of it to rig..
Will check the Chris's scheme as well, and advice you in case of news.

73s
Claudio"

Claudio to be quite frank I did some experiments with the a transformer in/out version Linvill NIC a couple of years ago. I put the project on the "back burner" because of instability issues and pursued work on lower noise Fet amps for my loops.

Notwithstanding the above; time permitting I still prepared to experiment with NICs. Its a very interesting subject.

"Check the phase connections of T1. If you have it backwards, then you won't see a negative inductor.

Chris"

Chris, T1 is bifilar wound with red and orange coloured wire.

The windings into the core are orange to Q2 Collector/Base with the coresponding red wire to Vcc.
Out of the core, orange connects to R1/C2. The red wire goes to Q1 Collector.

This is correct to achieve the phase reversal.

However, I did reverse the red wires as a sanity check. It still doesn't work.

An old audio trick for low level, low impedance sources is to lead off with a PNP transistor, the PNP complement of the one you are using would probably be a good starting point .... If you look at the NF of complementary transistors you'll find the PNP will almost always have the better NF, sometimes by as much as a half. If you look at schematics of 'transformerless' balanced microphone preamps you'll almost always see a pair of PNP's up front for this very reason

For instance (and if memory serves me) a 2n4401 has a NF of 1db while it's PNP complement the 2n4403, has an NF of 0.5db .... Maybe you'll get lucky and can lower the resistor values too (Then again maybe the opposite will happen)

Just something to think about

JR

You should look at the 2N5087 (PNP) and 2N5089 (NPN). I have used these parts in low noise audio applications and they work very well. They have better noise figures than the BC550. ft is 300-400MHz at 10mA collector current.

Andy,
you are right: up to now the "classic" way seems to be the better one, may be I cannot agree about stability, if you use extensive simulations (but you've to be skilled on this), you will discover unstability before to mount your circuit, my NIC as shown in the scheme is conditionally stable for sure, simply because it is a partially compensating NIC, closed to controlled impedances.
We have to go on, as you said the subject is very interesting.

That was an aspect of the circuit I found that caught my attention. The open loop gain is (hfe-2)/hfe), so it is unconditionally stable. You can make it unstable by changing the turns ratio of T1 to 2:1.

Hi All,
I am contemplating erecting a rotateble Flag type antenna but
some of the Internet sized versions assume you have a huge plot
of land not a suburban UK garden !!!!
Anyone have ideas from experience of more practical sizes to
make rotateable ??????
Many thanks,
72, Brian, GØNSL.

From: Chris Trask
Topic: 9360 Message: 9360

I removed both of the files related to active negative inductors from the group files section. A revised version of the one active file can now be found on my web page at:

http://www.home.earthlink.net/~christrask/Paper028.html

I corrected some spelling errors, and added a short discussion of a stable active negative inductor that uses a single transistor and a transformer. The realization adds a second transistor for biasing. I also added a short discussion about selecting transistors for the two realizable circuits.

I have few naked coils for half wave dipoles. I'd like to measure the coil characteristics to insure I use them properly and duplicate home-made replacement coils.

How do you measure:
1. resonant (center frequency)
2. Q 3db points (band width)
3. Inductance L

I have a GDO, MFJ-269, Spectrum Analyzer, and more.

Brian,

I've built several versions of the basic triangular version. The smaller one had a 10 ft horizontal baseline and 5 ft vertical support with a terminating resistor at one corner and the feedline connected at the opposite corner. This one was located on a rotor on the roof of the house. Another version had a 16 ft baseline and 25 ft vertical support atop a rotatable 50 ft tower. With the 'termination' resistance adjusted for maximum front-to-back, realistic values of 20 to about 30 dB F/B ratios were measured. These values were consistent with NEC modeling done prior to build-out.

Hope this helps.

Alex

9368. A somewhat asymmetrical loop. . .

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-02 21:15:43 UTC
From: Phil
Topic: 9368 Message: 9368

Well, today I bought the PVC pipe for the tuned loop antenna. The plans were to make it an "X" (Actually a "+") with four 3 foot cross-arms, all joined in the middle with a "PVC 4 way cross section". As mounted it would be a "Diamond" shape. I needed to use 1 1/2 inch Sched 40 PVC pipe to allow a standard TV mast to be run perhaps halfway up the center so that could be inserted into the rotator.

Well, NONE of the hardware stores in this town has the four way cross section in a size to accept 1 1/2 inch PVC pipe, just in smaller sizes. So, my ONLY alternative was to use two "Tee sections", mounted one above the other for the two horizontal cross arms. Of course, right off the bat that means that it won't be exactly "square" as one horizontal arm is 5 inches higher than the other.

THEN, when I was putting it together and cut all the sections, the top three arms were all cut to the proper 32 inches (allowing for the additional space occupied by the Tees and Elbows etc). Then I 'somehow' cut the lower section to 36 inches and had it glued in place along with the bottom Tee section BEFORE I noticed it (sweat was pouring into my eyes and my vision was a bit blurred anyway).

Well, if it were ONLY the one tee section I needed to replace I'd have just cut it out and bought another one. BUT that Tee section was "pre-assembled" (read glued) with the pre-amp section and housing all assembled. I used a PVC Tee, caps etc to house the pre-amp as I figured it would be more weather-tight and sun-proof than a cheap project box from Radio Shack.

It'd cost too much to buy all the fittings just to shorten the bottom section some 4 inches (All the PVC pipe, fittings etc cost me nearly $60 as it was, but I bought more pipe than I needed as it was cheaper to buy the "pre-cut" lengths than to have them cut it to length).

YES, I could have built it in a cheaper manner, just the cross-arms with no cross bracing etc, but we get a lot of gusty wind here, and that along with high temperatures quickly takes it's toll on unsupported PVC structures.

ASK ME HOW I KNOW THIS :(

Oh well, the asymmetry (elongated diamond with longer lower section) shouldn't have any effect on it's electrical characteristics or performance as a loop antenna. If anyone sees it and asks I'll just tell them that it was designed that way to "Suck the waves in better" ;-)

Coincidentally, I was just on line today looking for exotic PVC fittings
to build antennas with. The 4 way cross you were looking for is
available in some retail stores, but going on line you can get
a 5 way side outlet cross, or even a 6 way junction. They sell these
fittings for construction/furniture as opposed to plumbing. Google
"5 way side outlet cross" and you should get several vendors, such as
formufit, flexpvc, pvcfittings direct, and US plastics. Lots of
interesting parts for making loops. In a 4 way cross, you can get
up to at least 4 inch fittings on line.

Thank you, I DON'T know why I didn't think of that (too simple I guess :) Anyway, I did it and it's more symmetrical now with just the offset horizontal arms making it a slightly "squashed X".

I also got the 1 inch cross braces in place now so that it's much more rigid. I didn't want it swaying in the wind as I figure that would put more stress on the rotator and support mast. Since it'll be above the roofline of the mobile home it'll see some pretty vicious wind gusts.

The frame is completed and now all I need to do on that part of the job is to insert and secure the TV pole, then wind the 22 turns of 18awg enameled wire and wire it to the varactor tuned pre-amp module.

I'm not as young as I once was and so rarely work on it more than an hour or so at a time (and my work is slower). There was a time the entire job would have been completed in a day, maybe two at the most.

Then the fun job of mounting the rotator to the mast and getting the whole assembly up in the air begins. . .

9372. My new Loop antenna is completed and installed

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-09 00:39:07 UTC
From: Phil
Topic: 9372 Message: 9372

OK,
Today I wound the coil on the loop frame, installed the rotator and then had the neighbor help me get the entire thing up on the roof and installed on the Push-up TV mast. That part was a bit of a pain because the top section of the mast is jammed in place and won't go up or down any. That meant that we had to lift the entire loop antenna up high enough to get the rotator to slide over the mast. Luckily I had the foresight to install the rotator on the loop mast BEFORE trying to get it into place or we never would have got it up. A LOT of really hard work for two old pharts (neighbor is 62 and I'm 69)! I just soaked under a hot shower and took two extra strength Tylenol capsules, but I bet I'll still feel it later.

It is wound with 22 turns of 18AWG Enamel Insulated solid wire, it's 4 feet on a side (six feet across corner to corner). I used Beautician Wide Toothed "Styling Combs" as wire spacers, then used a short section of skinny PVC pipe halfway down each leg to space the turns further apart (sort of a "basket weave").

That installation on the mast was the only really hard part, the rest, including winding the coil was a piece of cake in comparison.

BEFORE winding the coil on the frame I had the forethought to test the loop amplifier and varactor tuning unit. I did that by connecting a small ferrite loopstick where the main loop would connect, then tuning the Icom R-75 to the MW band to see if the electronics worked OK. They did.

Testing the loop everything works well. It tunes about 175kHz to 450kHz. The signal it puts out on the stronger 24/7 beacons runs between 20-30 dB stronger than the three foot Ratzlaff which is up at 35 feet AGL, but the Ratzlaff whip has a MUCH better signal/noise ratio. That's NO SURPRISE as it's noise floor dropped dramatically when it was relocated from the spot where the loop now resides to it's new location. I could probably lower the noise a bit by raising the loop, but I DARE NOT put it up any higher than it now is.

Also, the loop amp has more gain than needed, I could have probably just used a FET Follower buffer only and didn't need the following Bipolar Emitter follower. It doesn't hurt anything as it doesn't overload, just has a lot more gain than is needed on this size of a loop.

ONE GLITCH: It works quite well, but it DOES NOT have a deep null like I've experienced with other loops. In fact, it only has about a 1 "S" unit change when turning from end on (where the peak should be) to flat side facing the beacon (where the null should be). At least that is how

it works with the 24/7 (groundwave) beacons. We'll see what happens at night time.

I suspect that must mean it has poor rejection of the "E" field and is sort of acting like a "Tuned Voltage Probe", not just responding to the magnetic field. I don't believe that there is anything I can do about it now as I'm NOT about to take it down again for modification. . .

OK, I took a LOT of pictures of the loop, both while it was still on the ground as well as up in it's operating position. You may see the picture at my NDB Audio Archive (I made an album just for them).

Hi Phil

The antenna looks great!... Got a few questions....

You probably bought the pipes from a big box store. I recall when making PVC chairs, I saw nice cross tee with 4 connections. It would have been perfect for this project. One of my questions... Why the screws on the joints.... Wouldn't the PVC glue hold the joints? Or were you concerned that strong wind would blow it apart? IS that why you used a double frame? Would a single pipe and a tee end suffice?.. (4 ft sides on your antenna?)

You've answered the obvious, that a loop up on a pole mount or outside when your inside, will definitely need a rotor...($$$). For a small loop I was thinking of using a servo and a chain gear, run by an Arduino maybe.

Best Regards

Subject: [loopantennas] My new Loop antenna is completed and installed

OK,
Today I wound the coil on the loop frame, installed the rotator and then had the neighbor help me get the entire thing up on the roof and installed on the Push-up TV mast. That part was a bit of a pain because the top section of the mast is jammed in place and won't go up or down any. That meant that we had to lift the entire loop antenna up high enough to get the rotator to slide over the mast. Luckily I had the foresight to install the rotator on the loop mast BEFORE trying to get it into place or we never would have got it up. A LOT of really hard work for two old pharts (neighbor is 62 and I'm 69)! I just soaked under a hot shower and took two extra strength Tylenol capsules, but I bet I'll still feel it later.

It is wound with 22 turns of 18AWG Enamel Insulated solid wire, it's 4 feet on a side (six feet across corner to corner). I used Beautician Wide Toothed "Styling Combs" as wire spacers, then used a short section of skinny PVC pipe halfway down each leg to space the turns further apart (sort of a "basket weave").

That installation on the mast was the only really hard part, the rest, including winding the coil was a piece of cake in comparison.

BEFORE winding the coil on the frame I had the forethought to test the loop amplifier and varactor tuning unit. I did that by connecting a small ferrite loopstick where the main loop would connect, then tuning the Icom R-75 to the MW band to see if the electronics worked OK. They did.

Testing the loop everything works well. It tunes about 175kHz to 450kHz. The signal it puts out on the stronger 24/7 beacons runs between 20-30 dB stronger than the three foot Ratzlaff which is up at 35 feet AGL, but the Ratzlaff whip has a MUCH better signal/noise ratio. That's NO SURPRISE as it's noise floor dropped dramatically when it was relocated from the spot where the loop now resides to it's new location. I could probably lower the noise a bit by raising the loop, but I DARE NOT put it up any higher than it now is.

Also, the loop amp has more gain than needed, I could have probably just used a FET Follower buffer only and didn't need the following Bipolar Emitter follower. It doesn't hurt anything as it doesn't overload, just has a lot more gain than is needed on this size of a loop.

ONE GLITCH: It works quite well, but it DOES NOT have a deep null like I've experienced with other loops. In fact, it only has about a 1 "S" unit change when turning from end on (where the peak should be) to flat side facing the beacon (where the null should be). At least that is how it works with the 24/7 (groundwave) beacons. We'll see what happens at night time.

I suspect that must mean it has poor rejection of the "E" field and is sort of acting like a "Tuned Voltage Probe", not just responding to the magnetic field. I don't believe that there is anything I can do about it now as I'm NOT about to take it down again for modification. . .

OK, I took a LOT of pictures of the loop, both while it was still on the ground as well as up in it's operating position. You may see the picture at my NDB Audio Archive (I made an album just for them).

Bill,
In the posted text you say that the 5ft x 3ft loop has ' two windings of No 20 magnet wire
'
but opening the file it shows 5 turns on one side and 1 turn on the other, does that equate to the two windings.
Could you clarify please as I like the compact rotatable design ?????

Hi Phil, Phil here,
I'll try to answer your questions.

When I was purchasing the supplies for my loop I looked for a 4 way "cross section". The only ones in this town were for smaller diameters of PVC pipe. I wanted a diameter that was large enough to let the mast section slide part way up the center section, as well as be rigid. Later I was told of a couple on-line suppliers that had the cross section, but the loop frame was already build, and I really didn't have the funds to start over again (I sold my Grundig S750 to finance this project).

As to the reason for the screws. Yes, the glue would have 'probably' held it OK, but I had an almost full box of deck screws and I wanted to be sure that the loop held together and didn't come apart. While we don't get hurricanes or anything, certain times of the year we do get some pretty good winds with very high momentary gusts. Before I had the vinyl roof laid over the sheetmetal one (it had developed pinhole leaks), a good wind gust would sort of "raise" the roof a bit and you'd hear these noises of the sheetmetal flexing (hard to describe).

Also it gets quite hot here and some PVC pipe projects in the past have "sagged". That combined with "flopping around" in the wind I didn't want to take a chance. I toyed with the idea of a single cross section with end Tees, But with a need for 22 "wide spaced" turns I figured out that they wouldn't fit on a single Tee section (not wide enough), and extending the Tee with a short section of PVC pipe would make for an uneven winding surface.

So I came on the idea of the little arms, each with a slot cut in it and a "Styling Comb" inserted as a wire spreader. Some expanding foam sprayed in each arm hold the combs in place, and to strengthen the weakened arms (cutting the slot weakened them) a second cross section of smaller diameter PVC pipe was used to strengthen it. And that "cross brace" adds a great deal of rigidity to the entire unit, something I was looking for so it wouldn't "flop in the wind".

And finally, some Silicon Rubber (RTV) on each comb and spreader insures everything stays where it should, as well as sealing certain things (like the wire holes in the top of the amplifier section).

Which brings up another point. to make sure that there is no condensation and water buildup in the amplifier section, the bottom hole where the control wire exits is oversized and NOT sealed so as to allow any condensation to drain (and the amplifier PC board is longer than need be to raise it above the floor of the amplifier housing). No need

for moldy-green circuit boards :)

9381. Dual Transistors for Active Negative Inductors

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-09 17:39:20 UTC
From: Chris Trask
Topic: 9381 Message: 9381

While searching for dual transistors that are suitable for use with the active negative inductor circuits I came up with, I came across some interesting offerings on eBay. Specifically, there is a seller in Canada who has MBT3904DW1 and MBT3906DW1 devices available at very reasonable prices. And there was also a somewhat interesting FMW2 device, which is a pair of 2CS2412 NPN transistors with a common base connection. These are not monolithic duals, but are instead a pair of individual die on a single carrier. Usually, devices such as this are comprised of two die that are immediately adjacent on the wafer, so their characteristics are fairly well matched, certainly better than using two separate devices.

I also came across the MBT3946, BC846BP and BC847BP, which are NPN/PNP complementary pairs. Those may prove useful for IMD compensation schemes.

Chris

To clarify as requested; There are two windings of AWG #20 magnet wire, one five turn winding and one one turn winding. The five turn winding is tuned with a three section variable capacitor, 397 pf each section. this three section variable capacitor is housed in a metal box an connected to the tuned winding with a length of coax of known(measured) capacitance. I can select one section, two sections or three sections in parallel. There are some additional capacitances switch selected to extend the tuned range lower in frequency(see the schematic). The five turn tuned winding is 2.5 inches from and parallel to the one turn winding which offers an approximately 50 Ohm impedance to the antenna input terminal of my Ten Tec RX320D receiver at 375 kHz. The 2.5 inch separation was arrived at by repeated tries with the LTSPICE IV model which indicated to me which numerical value of coupling coefficient was optimum. I then used equations from the cited Terman handbook to calculated the separation in inches. Before I put this loop antenna behind a bookcase I did some experimenting with its directionality. At best it's broadly directional. It's now permanently oriented east-west which seems to work well. I don't have radiant barrier in my house, so I do receive some with indoor antennas. My other antenna is an eight foot length of aluminum angle stock leaned in one corner with a single 2N3819 JFET "impedance transformer". It's not bad above 3 mHz, although the one turn winding of the above described two winding loop has lower noise and stronger signals at 9 - 10 mHz and 15 - 17 mHz. I have a "hard mounted" antenna selector switch which enable rapid comparison. Bill Young WD5HOH

Hey, Phil! Looks great!

Paul - AE5JU

9390. small (magnetic) loops and tuners.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-10 13:55:28 UTC
From: billnopic
Topic: 9390 Message: 9390

Morning all,
I am new to HF and have to struggle with Attic Antennas. I have a relatively large 86 foot horizontal loop in the attic and it tunes fairly well with my SGC-239 Tuner.

I am interested in trying a small loop. One that I may be able to rotate.

When I look at small loop writes ups, invariably there is some kind of "network" required. My one simple question is: Can I build a small loop and tune it with one of my tuners and forget these "networks"?

Thanks
73
Bill

9391. Tuning a magloop

Yahoo group: loopantennas (2008 — 2012)

From: lughi
Topic: 9391 Message: 9391

I want to make a magloop and put it up in a tree if i make it for 20m by using a halfwave length. do I need the tuning cap if I already have a tuner in use in my shack?

I made a 40m loop using welding wire and fiberglass tent poles. It work good but I need to put it higher than 20'. Thanks KD0KNL Lewis.

I bought myself one lot each of all of these. Modelling my first negative inductor on PSpice with the 2N3904 shows that for a 1-ohm source and load the performance should be flat out to 15MHz, with 2-ohms out to 29MHz, and with 5-ohms out to 45MHz. I'm thinking of using one of these initially in place of the varactors in my remotely tuned antenna:

http://www.home.earthlink.net/~christrask/Varactor%20Tuned%20Loop%20Antenna.pdf

Digikey and Mouser also have dual transistors, in both surface mount and leaded format, in prices that vary between more expensive and less expensive than the auction site. I'm not recommending one source over the other and I haven't compared specs with the part Chris found. I just did a quick search to see what options I had and was surprised at how much discrete stuff is still available from current production.

The MBT3904 series is available from ON Semiconductor and you can order samples.

I looked through Digikey and Mouser and came up with the BFM505 and DMC206E2 as being suitable candidates for the active negative inductor circuits. Not exactly cheap, but they both look like good performers.

I have difficulty recommending any of the NEC/CEL monolithic duals as I've noticed over the years that their offerings are not exactly stable.

Chris

Hi Chris,
I've been out of the topic because of my job, but now I'm coming back again.
Are you looking for a NPN/PNP matched pair ? Or simply two matched NPN for the Linvill's type NIC ?
During the gaps of my job I found very interesting SiGe transistors from Infineon (we are using them at 15 Ghz) namely the BFP740 or BFP420, they have high Ft and low noise, I suspect that they will work well in some of the schemes we've worked up to now including the Linvill's one. I suspect this because in my simulations I can see the input noise rising according to the gain fall due to Ft limits...will keep you informed.
Anyway I'm in stall because of noise and IMD...!

My question must have been obtuse?

Can anyone give me a quick answer?

I am using an SGC-239 Remote Tuner. On the SGC website they show their tuners directly feeding small loops.
But this is the only place I have ever seen this. Every other Small Loop mentioned on the web has a VariableCap/network associated with it???

Ciao !
I would try to build a breadboard of "small antenna" @ 27 MHz and I would like to undertake two different options for active matching, to be compared as follows :

Option a) using MAX2180 (AM section) antenna amplifier

Option b) using BFM505 for practical NIC circuits shown by Chris:
Fig.5 on pag.5 of "Active Negative Inductor" Report
http://home.earthlink.net/~christrask/Active%20Negative%20Inductors.pdf
Fig.6 on pag.5 of "Linvill feedback amplifier" Report
http://home.earthlink.net/~christrask/Linvill%20Feedback%20Amplifier.pdf

I would be truly glad of receiving your advise

Warmest ciao !
Roberto

Bill, small loops have very small feed impedances, less than 1 ohm, in many cases.
The SGC tuners are not made to handle this low impedance.
SGC RECOMMENDS AN 80 FOOT CIRCUMFERENCE LOOP.
You dont specify what bands you want to operate.
Perhaps a loop about 1/3 wave at 20 meters, aprox 20 feet circumference, would be 6.4 feet or about 2 meters diameter.
That would be rotatable and probably matched by the tuner on 20 to 10 meters.
On 40 it requires about 180 pf cap to resonate and would have 15% efficienc, y though the tuner may match it on 40 and 30 meters.
Also the small loops develop very high voltage at the tuner and it may not work with more than qrp power.

I have done a considerable amount of modeling to determine where the active negative inductors I described would work best. The usable bandwidth of the circuit of Fig. 5 is directly proportional to the embedding impedance. In other words, the usable bandwidth increases as the embedding impedance increases. There is a limit to this imposed by the transistors, and I found the for HF frequencies an embedding impedance of about 5 ohms works best.

The combination I would recommend would be to use the negative inductor circuit in a balanced configuration, coupled in place of the varactors in Fig. 4 of my earlier paper on varactor-tuned loop matching networks:

http://www.home.earthlink.net/~christrask/Paper011.html

To make a balanced negative inductor for this application, add a third winding to transformer T2 of Fig. 5, using a trifilar twist of wires to ensure good coupling and balance. Be careful to get the correct phase connections when doing this. It might be prudent for me to add this application to the negative inductor paper as that was the intended use from the beginning.

Chris

Don,

Thanks for the reply.

Here is where I am getting my inspiration (could be stupidity too:)
SGC website in the StealthBook.PDF File on page 23.

http://www.sgcworld.com/Publications/Manuals/stealthman.pdf

A 4X4 pvc frame with the 80 feet of wire you mentioned. Does this not constitute a "small loop"?

As to which Bands, I am too new to HF to have a particular requirement, except I did want short (100-500 miles) range capability on 75 meters, directional. Hence my quest.

My thought was to build this as a "delta?" triangular loop with the PVC pipe. I can actually make it proportionally somewhat bigger than a 4X4 square or rectangle if that helps and still be able to mount it on a rotor. And fit in my attic.

Do you think this is feasible? I don't mean to ignore your points in your email, but not sure it all makes sense yet:) Although failing everything else, I will try your:

"Perhaps a loop about 1/3 wave at 20 meters, aprox 20 feet circumference,
would be 6.4 feet or about 2 meters diameter."

Thanks again.
Bill

At my last apartment, in NJ,I had a 5 foot square with the 80 feet of wire. That was the size of the window frame. It loaded 80 to 10 meters with the SG-237. When I was moving I found I had a Low Pass filter under the desk in the line. No wonder 6 meters wouldn't load.

The important thing is the 80 feet of wire.

Only worked Cuba on ssb and psk31 with the bands being dead at the time.

I just uploaded a schematic into the group files section to help illustrate this, and the announcement appeared about a minute ago. I'll add this schematic to the active negative inductor paper later, along with further comments about the selection of transistors and other details.

Chris

Thanks Ken.

So it was just wound around the square??

I am plotting and planning my new loop.....:)

Yes. Here in Colorado I tried a 7 foot square loop and it did not do as
well as the 5 foot square and then the SGC-237 had to be sent for repair.
I purchased a MFJ mag loop and still trying to get that running. I have
to move it around in this apartment/balcony and play with it.

In time. I had a real nice dx station in NJ and I really haven't gotten
back into radio. Maybe when it gets to below freezing and don't go out
I will get the 'wanting' back.

9411. Re: [loopantennas] small (magnetic) loops and tuners.

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-17 03:46:16 UTC
From: Don Sanders
Topic: 9390 Message: 9411

Bill, I downloaded the Stealth book and reviewed the pictures and descriptions of their loops.
Yes we are talking about a different antenna from your first post.
I guess a loop 5 foot on a side is smaller than a loop 20 foot on a side.
A 4 turn loop is different from a 4 sided one turn loop.

A small loop is usually refering to a magnetic loop of .1 to .3 wavelength one turn circumference.
What they are talking, and you, about is an 80 foot wire coiled into 3 or 4 turns.
OK , well the smaller the turns, tyhe less length in the sides and the lower efficiency.

For use at 80and 40 meters you should consider making the loop as LARGE as possible.
Consider a one or two turn loop horizontal in the attic area. This would be rectangle of 40 feet
in each turn and possibly 15 foot by 5 foot or 10 by 10. This will be much more useful for contacts.
and it will be omnidirectional. No rotation needed.
For 20 and up it will also work but probably not as well as a tuned dipole.
A 4 turn loop 5 foot on a side will work but you will get some weak signal reports.

Thanks Don,

I will try to absorb the info after some coffee:)
It starting to make sense and I will experiment a little and see what I come up with.

I did send an email to SGC and here is what they said.

"Our couplers work best with basic antennas. Having added coils, caphats,
other capacitive elements, etc. generally do not allow the coupler to perform
properly. The SG-239 will work well with a loop antenna. Only issue
is it's physical size. For operation on 160m the couplers needs a minimum
100 foot antenna - this equates to a 200 foot loop. You can accomplish by
having two turns on a 25 foot square frame. For a smaller rotatable frame then
simply use more turns. To help eliminate any RF issues that could develop
it is best to feed it with a short run (3 - 10 feet would do)of 300-600 ohm
ladder line style lead. 16 Ga wire is minimum size. Copper tubing
can be used but the physical size then becomes an issue."

So all good food for thought. Also had a couple of other readers respond with good info and observations.

Thanks again!
Have fun.
Bill

Thanks Ken,
I am cussing and discussing with myself.
Trying to put it all together and come up with a good antenna based on the info everyone has provided.

have fun

9414. Loop gain lower when wet?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-22 21:42:27 UTC
From: Phil
Topic: 9414 Message: 9414

Hi All,
The tunable LF loop that I put up a couple weeks ago seems to be affected a bit when thoroughly wet. Just possibly there may be some additional path losses over the roughly 65 miles affecting the readings too.

In the AM mode FCH-344 typically reads about S9+50dB on the R-75 S meter, with an occasional kick up to S9+60 on modulation peaks. Right now we're having a nice heavy rain storm and FCH-344 is reading S9+30, peaking to S9+40 on modulation peaks.

Oddly enough, the tuning of the loop (Voltage tuned via Varactor) doesn't seem to have changed, or, if it did, not by very much (it tunes very sharply around that frequency). Perhaps the difference is due to coil dielectric losses of water versus that of air, though the 22 turns are rather wide spaced.

As a reminder of what it looks like, see the pictures here. . .

What bias voltage and current are you using?

Looks like the solid line is signal current and the dashed line is phase.

If you place a 5-ohm resistor in series with the signal source you should see better results. My simulations showed this impedance to be close to ideal.

Chris

Dear Chris,
the series-resistor of 100 Ohm gives Collector currents of 60 mA, therefore, leaving the supply voltage at 7 V and increasing the series-resistor on the collector up to 470 Ohm, we get 13 mA (see the enclosed simulation results of DRAFT2)
Regarding the Source resistance of 5 Ohm, I have replaced the former small-signal Current source (Itest1) with a small-signal Voltage source V2 in series with the required 5 Ohm resistance. The result is here enclosed in DRAFT3.
It seems this circuit shows "ideal inductive" behaviour at lower frequencies under 10 MHz, ...and "non-Foster" behaviour in the band 30MHz-50MHz..isn't it ?
Warmest regards,   Roberto

9418. Actual comparisons of my Loop antenna VS. the Whip

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-10-27 06:27:42 UTC
From: Phil
Topic: 9418 Message: 9418

Tonight I conducted a number of experiments comparing the two antennas. I tuned FCH-344 which has a reasonably strong and steady signal here, then first checked the loop by rotating it. Even though the signal strength of FCH didn't seem to change much as observed on the "S" meter I could get a definite null on the power-line noise as I turned it. The quietest spot seemed to be almost due North/South, which is basically the same results I saw with various loop antenna experiments shortly after I moved in here almost 13 years ago.

Then I set the loop for the quietest background and switched between the Loop and the Ratzlaff active whip. Keep in mind that the whip is located about 21 feet higher than the loop and is in a MUCH quieter location. Also, the loop has much higher gain than the whip due to it's being resonant, and I inadvertently used an amplifier with more gain than was actually needed.

That recording starts with the whip, switches to the loop, back to the whip, then finally the loop again.

And finally, these tests were run in the AM "wide" (6kHz) mode as the difference is more noticeable than when using the narrow CW mode combined with narrow audio filters. . .

Hear the tests here (pictures of the two antennas are also on the site in separate albums).

Sounds very similar to my experience here ,i'm still learning the in-and-outs of phasing but it has helped my dx a lot ,in fact last night i heard a station from California (1kw 1212miles) that i would have never heard without the phaser and antennas i have ,gl with your setup :)

9420. again: SPICE modeling Dual Transistors for NIC Inductors

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-03 20:57:14 UTC
From: Roberto
Topic: 9416 Message: 9420

Ciao Chris,
I have set the same values of your SPICE_circuit simulation just for computing the actual frequency response in two cases of interest, using 2N3904 and 2N2222 transistors. It seems that the bandwidth is limited to frequencies between 100KHz and 500-600KHz where the first resonance occurs (see the "continuous line" impedance reaching its minimum in the 2N2222 circuit model while the "broken line" of phase is abruptly changing of 180°. NOTE that also in the 2N3904 circuit model you get anyway this abrupt phase change of 180°)

I will try further freq.response simulations using different values of primary/secondary inductances of transformers

Find enclosed my results in PDF, together with the "LTSpice model" of 2N2222 circuit. Your comments and valuable suggestions are welcome !

Warmest ciao ! Roberto

Kindly see the FILES section for getting these simulation results

9422. To Balun, or not to Balun, that is the ?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-05 17:04:08 UTC
From: Fred
Topic: 9422 Message: 9422

Hey gang,

One of the trees holding my 80 mtr horizontal loop came down (thanks to Sandy), so this weekend was spent workin on the ole antenna. I've always just fed it with coax, and was reading about people feeding them with "Ugly Baluns," which is just about 20' of coax wrapped around 4" pvc.

Then I thought about commercially made baluns, and wound up looking at a DX engineering balun. Question is, the dx engineering option is close to $100. The Ugly Balun is a lot cheaper. I remember reading that you don't want to use a balun on a loop fed with coax, so now I'm at a loss.

At this point I'm thinking I'll just continue to use what has been working, just coax right into the antenna. Can't help thinking I could squeeze out a little more performance with a balun..Any advice? Thanks in advance.

73's de KB8VIV

P.S. I use it from 10-80 meters

The "Ugly" balun is best described as a choke, rather than a balun. It's function is to reduce RF on the shield. I used one for a while on a multidipole, and while it worked fine on the upper bands, when using my amp (AL-811H at anything over 400 watts) I got RF in the shack on 80/75 meters.

Snap on Ferrite beads worked far, far better. I used the RCT-2 from Fairite, and 15 beads seemed to work the best.

Ferrite beads is also what is inside most "1:1 Current Baluns". Same thing as what I had, only inside a PVC tube.

But neither the beads nor the "ugly balun" (choke balun) provide any impedance matching. Many use a 4:1 current balun for loops.

Put them on up by the feedpoint. The RCT-2 fits the .240" coax I have, which is LMR-240. This size also fits RG-8X.

Also, I have two extension cord reels, each with 50' of RG-8X flexible coax. I keep these for portable / field day operations. I have 10 beads on one end of each of these reels.

Note that you need more beads for lower frequencies, fewer beads for higher. 1 or 2 beads is sufficient for a 2 m / 70 cm J-pole, for example.

8 to 10 beads for 40 meters on up. Etc.

The FairRite RCT-4 fits 0.400" coax, 9912, LMR-400, RG-8/U, etc.

For these beads there are several sources:

www.hamcity.com and on the left click "Chokes".

https://www.hamcity.com/store/pc/Chokes-RFI-c655.htm

I see only the RCT-2 listed at Ham City (Jun's Electronics) at this time. They used to sell two other sizes.

http://www.newark.com/ferrite-beads?isRedirect=true

At Palomar Engineers:

http://palomar-engineers.com/ferrite-beads

The FSB-1/4 is the FairRite RCT-2

Also look here:

http://palomar-engineers.com/1-1-balun-kits

This requires you to install before putting the connector on the coax.

And also at Radio Dan:

http://www.radiodan.com/Henry/parts/RF_chokes.htm

Put them on up by the feedpoint. The RCT-2 fits the .240" coax I have, which is LMR-240. This size also fits RG-8X.

Also, I have two extension cord reels, each with 50' of RG-8X flexible coax. I keep these for portable / field day operations. I have 10 beads on one end of each of these reels.

Note that you need more beads for lower frequencies, fewer beads for higher. 1 or 2 beads is sufficient for a 2 m / 70 cm J-pole, for example.

8 to 10 beads for 40 meters on up. Etc.

The FairRite RCT-4 fits 0.400" coax, 9912, LMR-400, RG-8/U, etc.

For these beads there are several sources:

www.hamcity.com and on the left click "Chokes".

https://www.hamcity.com/store/pc/Chokes-RFI-c655.htm

I see only the RCT-2 listed at Ham City (Jun's Electronics) at this time. They used to sell two other sizes.

http://www.newark.com/ferrite-beads?isRedirect=true

At Palomar Engineers:

http://palomar-engineers.com/ferrite-beads

The FSB-1/4 is the FairRite RCT-2

Also look here:

http://palomar-engineers.com/1-1-balun-kits

This requires you to install before putting the connector on the coax.

And also at Radio Dan:

http://www.radiodan.com/Henry/parts/RF_chokes.htm

I use an "ugly balun" choke with my 40M horizontal loop positioned just under the 4:1 balun and get great matches from 40m up through 6m.

I use this balun directly connected to the loop:
Mod III 4:1 Tuner Balun 1.5 - 54MHz 5kw - #4124 (4124t - Studs on top)

73s,
Steve (KJ4WRK)

9429. 3m Diameter, 10Mhz, Magnetic Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-09 11:47:30 UTC
From: g3zxx
Topic: 9429 Message: 9429

Hi All,
Just a quickie, to advise, those that may be interested in Magnetic Loops, that I've been playing with 3m diameter loop, as an intermediate step to building a 6m Diameter version.
I've uploaded a website with all my constructional and test data, plus log book,etc., at:
https://sites.google.com/site/g3zxxmagneticloops/Home
<https://sites.google.com/site/g3zxxmagneticloops/Home>
The info may be of interest, to some, but I'd be very interested in receiving any feedback, recommendations or comments, on the un-conventional methods, I've used, prior to starting on the 6m version.
Thanks to all those who maintain the group.
Cheers & 73'sDave, G3ZXX.

Look at Arrow Electronics.

They surprised me a number of times on cost and service for ferrite material

Lower in price than the "regulars" that are recommended. They have the Fair-Rite 31 mix for the lowest cost (based on 5 websites I looked at before calling the search process "over".

For < 2MHz suggest to use 73 material, but look at specs for your application.

Hello Dave

Thanks for a well written and very informative article.

I have been playing with loops of various types / sizes for the last year. Right now I have 4 of them undergoing testing, of which 2 are mag loops. I am of the view that the ham radio community has always under estimated the loop. With JT65 and 20 watts I have made contact all over the world.

3 months or so ago I bought a badly damaged MFJ 1786X mag loop that I am restoring, paid £25 for it so if I fail it's not a catastrophe particuarly

Has anyone figured out the math to an UglyBalun, so we could optimize it for the bands we use it on? To me the UB coax appears to be 'short' a number of turns (coax length) for 60-160m use.

The current UB design looks to have coax near 40m 1/4 wavelength (if that is the correlation of the UB to frequency). Also the UB appears to have been designed around using it on a tri-band (10/15/20m) beam to replace the six-6" turns that Cushcraft A3/A4 and other beams require.

Th UB is not a balun that transforms impedance it is a choke keeping RF off the coax shield, retaining the integrity of coax function.

--- In loopantennas@yahoogroups.com, "tenorman1952" <tenorman1952@...> wrote:
>
> The "Ugly" balun is best described as a choke, rather than a balun. It's function is to reduce RF on the shield. I used one for a while on a multidipole, and while it worked fine on the upper bands, when using my amp (AL-811H at anything over 400 watts) I got RF in the shack on 80/75 meters.
>
> Snap on Ferrite beads worked far, far better. I used the RCT-2 from Fairite, and 15 beads seemed to work the best.
>
> Ferrite beads is also what is inside most "1:1 Current Baluns". Same thing as what I had, only inside a PVC tube.
>
> But neither the beads nor the "ugly balun" (choke balun) provide any impedance matching. Many use a 4:1 current balun for loops.

Hi Stephen, M0GWI.
Thank you for the feedback and nice comments, on the Magnetic Loop project <https://sites.google.com/site/g3zxxmagneticloops/> , much appreciated.
Like me, new'ish to this type of antenna .. hi.
It was only as a result of working some stations, on JT65a, with what I can only describe as "Stunning signals", that made me think about finding out more and eventually lead me to building my first experimental loop, just over a year, or so, ago.
Please let me (us all) know how the refurbishment goes.
Keep in touch.
Cheers & 73'sDave, G3ZXX <http://www.g3zxx.webnode.com> .

Ugly Baluns DO NOT work "as advertised".

I have tried many variations and evaluated them with an AIM analyzer and the choking impedance is unpredictible.

Get some 31 material ferrite clamp ons from Arrow Electronics (Fair Rite p/n) 0431177081

at $11.00 each

This will get it done, the ugly balun is VERY frequency limited and has little choking impedance.

Jim

Everett, I did take a look at the file you downloaded in the files section. These are really beautifully made antennas, it is always a joy to see at a job well done.

But, how did you arrive at the choice for the impedance ratio for the transformer from the single turn pickup loop to the coax.

As far I have understood from following this group for years a single small, untuned loop has a very low impedance, far lower than the 50 Ohms of the coax, but you seem to transform the pickup impedance down with a ratio of 3200/50? What am I missing?

Regards,

Cor Beijersbergen

Hi Cor,

Well there is no short answer. Anyway here is how I arrived at the 3,200/50 (64/1) ratio. I have been experimenting with both air loop and Ferrite Sleeve loop antennas now for the last several months. The problem that I keep running into was coupling. There is not much information that I could find on the subject. So I started experimenting with different approaches to couple up to the various loop antennas that I was experimenting with, without degrading the performance of the antenna.

So what I found out was that, in most cases, a one turn pickup loop worked the best, however, it still loaded the tank circuit, when connectedt to a 50 ohm load. So I started experimenting with matching transformers, first using toroids, then later moving to binocular cores. I started out using a 9:1 ratio and it helped, but there was still some loading of the tank circuit. I also had a ferrite rod, with a 5 turn winding, that was also connected to 50 ohm coax, that was used for inductive coupling. By using a A/B switch, I was able to switch back and forth between the two different coupling approaches. When I was using the ferrite rod coupling there was never an issue with loading the tank circuit.

Later I purchased a AC volt meter, with a RF probe. I connected the RF probe across the variable capacitor on the air loop, with it tuned to a local radio station. What I noticed was that when I used the ferrite pickup coil there was little, if any drop in the voltage, however, when I moved the A/B switch to the one turn coupling loop, with the 9:1 matching transformer, there was a very large drop in voltage. So this is when I decided to start trying higher ratios, going from the 9:1, 16:1, 32:1 and finally with the 64:1 ratio, I no longer saw much, if any voltage drop. I also noticed that I now had a higher S meter reading on my Icom R75, than I had using the ferrite pickup coil. In the past with the lower ratio transformers the S meter readings were always a little lower, that with the ferrite rod.

I told you that it would be long answer and not very technical, however, with a lot of work and experimenting I came up with a solution, without using the traditional amplifier approach to couple to a 50 ohm load.

In a message dated 11/13/2012 3:57:58 A.M. Central Standard Time, dx11@... writes:

Everett, I did take a look at the file you downloaded in the files section. These are really beautifully made antennas, it is always a joy to see at a job well done.
But, how did you arrive at the choice for the impedance ratio for the transformer from the single turn pickup loop to the coax.

As far I have understood from following this group for years a single small, untuned loop has a very low impedance, far lower than the 50 Ohms of the coax, but you seem to transform the pickup impedance down with a ratio of 3200/50? What am I missing?

Hello Everett,

Thanks for your elaborate answer. It is of value to me because it shows that an approach is possible that deviates from the loop antennas I have seen mostly, that is with one pickup winding feeding directly into 50 Ohm coax. The MW loop of Radio Netherlands is an example of that concept.

I suppose you have optimized for a minimal loading of the tuned LC combination of the receiving windings for the sake of a small bandwidth.

I wonder, you have made measurements of the voltage across the tuning capacitor at different transformer ratios, did you also take into account the S/N ratio of the received signal. You said the S reading was higher with the high transformation ratio, but that is not the same as a good signal quality.

In other designs one can see a one turn pickup loop with a diameter of 20% of the main loop. This might lead to the same result as your high-ratio transformer.

BTW. How are your reception results with these antennas? Did you do some serious listening yet?

Regards,

Cor Beijersbergen

Another general statement that does not hold true in many cases.

I analyzed the clamp on and solid ferrite core versus cost, and found, yet again, pricing does not only depend on "specs" or "efficiency.

You are correct in stating that for a given volume of ferrite material, an un-gapped (solid torrid) will give you higher "efficiency" (being defined as impedance per turn) at a cost of $XX.

If you look at the snap on cores, the volume of the core I mentioned is significantly higher (don't have the old analysis anymore), helping towards attaining the impedance per turn of the solid torrid.

Now, if you look at pricing, this is where the market comes into play. Fair-Rite has priced the snap on's that has only a small association with raw material costs. They threw a lot of ferrite at the big snap on to improve the impedance per turn, and determined their market would pay a slight premium for the convince of "snap on".

One could use the solid torrid rather easily for a new installation, but for existing installs, the snap on worked better for me.

Each case is different, and one should look at the major criteria involved in bringing a solution to the issue at hand.

I have a friend who likes to work the DOG (DX). He told me that I could be doing these types of analysis, measure actual performance with test equipment, and write mails like this, or I could be working the DOG.

He is at 8 band DXCC and on the door step (if not there now) of Honor Roll.

As you can see, I am still typing.............................

Hi again Cor,

To answer your question re: S/N, after deciding on the 64:1 Matching transformer. I saw no noticeable increase on the noise floor, by taking S meter readings, off station, between the ferrite induction coupling and the loop coupling, but as I mentioned, there was a slight increase in the S meter reading with the loop coupling versus the ferrite pickup. Probably the most notable change was the improvement in the tuning sharpness, which was now on par with the ferrite coupling. It is so sharp that I am considering adding resistor, with a switch, so I can take it the resistor in and out of the circuit, to kill some of the Q on some stations.

The performance of these two antennas is superior to any air loops that I have built to date, with my largest being 4'. The 4' air loop just used PVC covered 18 gage wire which was spaced on 1/4 centers, but it did not perform as well as the Hex loops. You might say why are they better and my only answer is that it maybe the Litz wire. The Hex MW antenna is quitter, has sharper tuning and has better rotational nulls and also does a better job on weaker stations. Also the Hex Loop had a wider tuning range than the 4' air loop, using the same Variable Capacitor, which again is because of the Litz wire, which has a lower distributed capacitance than the 18 gage wire, which also had more wire spacing than the MW Hex loop.

Two days ago I put up a 45' PAR type antenna (45' long end feed using a 9:1 matching transformer and grounded) and during the day the noise levels were so high that I was not able to pick up many stations, however, I was able to pick up many, many more stations on the MW Hex loop, which was in my basement. During the evenings the noise had quitted down and the Hex loop was working as well and sometimes better than the Par antenna. The PAR antenna did show a few more S units than the Hex loop, but with the higher readings so came the increased noise levels.

There was no comparison between the LW Hex loop and the PAR antenna, as I was hearing NDB's that were quite readable, that I could not even hear with the PAR antenna, night time and daytime. The way I constructed the two antennas did not make them work any better, than using some other types of construction, it was the Litz wire and non the loading coupling that made the big improvements.

Everett - I'm wondering if you experimented with the distance between the main loop and the one-turn pickup loop before trying the various transformers? These big loops have a huge field and I'm just wondering if it might be overcoupled in the present position and if setting it back further (perhaps inside the main loop) would result in less loading-effect when connected to 50 ohms?

For 80 meters, I would get two snap on chokes from Arrow (I ordered 10 as they are useful in other areas) and put three turns (remember that when the coax goes thru the core it is one turn, so three turns "look" like two loops), with each turn being 12 inch in diameter. Space the two cores about 2 feet apart. You want to keep the turns at a 12 diameter to keep the self resonance of the coax/core above 80 meters, and give you "enough" choking impedance on 80 meters, so the cores do not overheat.

And.....your constructive suggestion??

Jim
WA9ZBV

BTW, the Rs of the choke on 80 meters is in the 4K ohm vinicity.
How much power do you need to run to warm up bird's feet with 8k ohm (two chokes)???

It is engineering and math, and the number two is the same on earth as it is in another galaxy. What does your math say??

For 40 m on up, 8 snap on ferrite beads.

For 80 m on up, 15 beads.

Or a good 1:1 current balun.

For my antenna (fan dipole for 75/40/20 m) when running my amp, I am using a 1:1 current balun #823A from Clear Signal Products (aka the Coax Man) in Oklahoma City.

http://coaxman.com/showdetail.php?fetchitemnum=823A

The snap on beads got rid of the RF in the shack, but the balun works equally well. I use the beads now on reels of RG-8X for portable operations.

Paul,

What mix do you use and what is the mfg part number?

Have you measured the choking impedance vs. frequency of your set up, and if so, what were the results?

Tnx

Jim

Fair Rite RCT-2 snapped on LMR-240.

>
> Have you measured the choking impedance vs. frequency of your set up, and if so, what were the results?
>
> Tnx
>
> Jim
> WA9ZBV

No, I just kept adding beads until the "RF in the Shack" problem disappeared, and added a few more for extra. The symptoms were tingle from the metal mic (Heil HM-10) and a fluttering oscillation of my amp at anything over 350-400 watts on 80 meters. Also affected by proximity of the mic to the receiver (Ten-Tec Jupiter) and amp (Ameritron AL-811H), which are side by side.

No problems at 100 w, and when not using the amp.

I had a big bag of the Fair Rite RCT-2s, and kept putting on two at a time until the problem disappeared, then added a few more.

At the suggestion of very knowledgeable ham in these matters I contacted Clear Signal. The fellow there suggested their 1:1 Current Balun to replace both my fan dipole's center insulator and the beads. No problems since.

The FairRite Snap On Ferrite Beads are available from

www.hamcity.com (Jun's Electronics) RCT-2 for RG-8X and LMR-240, other 0.240" dia coax. RCT-4 for LMR-400, 9913, RG-213, other 0.400" dia coax.

https://www.hamcity.com/store/pc/Chokes-RFI-c655.htm

http://www.newark.com/ferrite-beads?isRedirect=true

http://palomar-engineers.com/ferrite-beads Scroll down to Split Beads. FSB-1/4 is FairRite RCT-2. FSB-1/2 is RCT-4.

9458. Function of Shielded Receiving Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-25 03:47:46 UTC
From: jurgen.brac
Topic: 9458 Message: 9458

Hallo folks,
I hope, there are some "experts" in this group to answer me a fundamental question and help me understand how loops work.

As protection against noise generated by modern electronic devices shielding a loop is recommended. But ...

...the alu caps of IF transformers in a superhet receiver prevent electric AND magnetic coupling between adjacent stages. So, how can an electromagnetic wave penetrate the loop shield and induce a current in the loop wires ?
I know, there must be a gap in the shield at the top, but normally there is also a hole on top of the IF cap. And the gap is only just a few millimeters wide. A wave, lets say 80m, cannot creep inside through a small gap like that.
What happens, when both sides of the gap are just a fraction of a millimeter apart ?

Looking forward to receive your "sophisticated" explanations,
this is Jurgen from Germany.

> As protection against noise generated by modern electronic devices
> shielding a loop is recommended. But ...

This is not the case. A shielded loop will not offer any shielding to external noise compared to any other type of loop. The shield refers only to the outer element...the one with the gap cut into it. The shield is in fact the actual 'antenna' part of the loop, not the inner conductor. Signals picked up by the shield are coupled into the one turn inner loop and then to the feedpoint.

Dear Chris,
I've built the circuit using two 2N3904, it's oscillating!

Thus, back to my LTSpice simulation now for checking transient behaviour (that is in time_domain for large signal) I found that instability affects such circuit configuration.

Therefore, if you simulate the behaviour in the frequency domain you get just small-signal response of the circuit and you cannot see this instability.

Look at my simulation result NIC_2N3904_INSTABILITY.pdf in the "Files" section, folder : LTspice_simulates_2-NPN_Neg_INDUCTANCE

I will send this result also by email, for your convenience...

Warmest ciao !

9462. Re: [loopantennas] Function of Shielded Receiving Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-25 11:30:59 UTC
From: Jack Smith
Topic: 9458 Message: 9462

Steve:

Isn't it the case that in the "near field" of two antennas, the normal electromagnetic wave "far field" simplification fails and one must consider separately electromagnetic and reactive coupling between the two? Reactive coupling being magnetic and capacitive.

As I recall my electromagnetic engineering classes (and it's been > 45 years), the strength of these various couplings varies with 1/R (electric or magnetic field associated with a propagating EM signal; energy is 1/R^2) and with higher orders (1/R^2, etc.) for reactive coupling. Hence, the transferred energy falls off rapidly for the electric and magnetic coupling, so that by about 1/3rd wavelength or so, spacing from the antenna, the EM field predominates and the normal far field rules become increasingly accurate. Wikipedia has a decent overview of this phenomena at http://en.wikipedia.org/wiki/Near_and_far_field

This non-EM coupling is also known as evanescent-wave coupling.

Hence noise between two close spaced antennas - one being a receiving loop and one being associated with a noise source - will couple by both EM and reactive coupling. The capacitive portion of reactive coupling between the source and receiving antenna will be reduced by loop shielding. Electromagnetic coupling (via the usual transverse radiating electromagnetic field) won't be reduced. In some cases, the predominant coupling mechanism between a noise source and a receiving antenna is capacitive coupling. That's certainly not universally the case, but it is in a sufficient number of cases to make a loop useful in reducing local noise pickup for many loop owners.

If the noise source is "distant," (distant being more than roughly 1/3rd of a wavelength) then noise is transferred through electromagnetic radiation and the loop will respond to it just as it does to a legitimate signal. But I don't think that noise sources close to a shielded loop- separation within the near field - work quite the same way.

This may be due to mismatch of the transistors. If the emitter resistance of the second device is larger than that of the first device you'll end up with a negative input resistance. Try adding a small resistance in series with the emitter of the first device.

Chris

Dear Chris, the circuit is oscillating even using its SPICE model (for transient simulation), actually in these simulations the two transistors are identical.
  Looking forward receiving your comments and suggestions Warmest regards,
  Roberto

This may be due to mismatch of the transistors. If the emitter resistance of the second device is larger than that of the first device you'll end up with a negative input resistance. Try adding a small resistance in series with the emitter of the first device.

Chris

9466. Re: [loopantennas] Function of Shielded Receiving Loop

Yahoo group: loopantennas (2008 — 2012)

GM Jack - I think that many amateurs struggling in today's growing noise fields often look to the 'shielded' loop as a possible cure for their rising noise floors (particularly for MW and LF) as it would seem a logical assumption based upon its name. There is no doubt an analytical case to be made for some specific types of closely coupled noise sources but in general, and it has been my practical experience as well, that my shielded loops offered no distinct advantages over my multi-turn air core loops when it came to neighborhood noises. Unfortunately I cannot speak from an engineering background but my understanding of these things is that in order to function at their best, construction tolerances need to be of a very high standard as well as the method of coupling, matching and feeding so as to maintain perfect balance throughout the system. With the amount of noise source crud flooding backyards nowadays, I think it would be almost impossible to determine which type of noise source might respond to high-tolerance loop construction, if any, and which would not. The ability to turn and null certain point sources might make the shielded loop builder a believer but I think in most cases, the same results could be achieved with air core as well. Perhaps my shielded loops were just too large or not as electrically balanced as I have tried to make them but this has been my experience over the past several years of using loops on LF.

What is the frequency of the oscillation? My simulation shows that there is a moderate potential for instability around 40MHz or so using the 2N3904. The solution to this is to place a resistor in parallel with the reference inductor.

9468. 140 ft loop plus Vertical

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-25 02:30:20 UTC
From: yioutta_99
Topic: 9468 Message: 9468

Hi,

I am new to the group and have a question. i have a 145 foot loop that i use on 20 meters. My signal goes Nw to SE. today i put up a 20 meter vertical dipole on the north side of the loop. The loop is a delta (3 corners) and is on a diagonal plane to the ground. The vertical is on the opposite side of the feed point corner of the loop. With both Antennas hooked up in parrell, i get a good 1.3:1 SWR and some good signal reports, but I have no idea what my pattern looks like. Is there a modeling software (freeware) that I can check this out on? Has anyone done this before?

Thanks

Steve

9469. loop antenna - has to be in resonance?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-11-25 08:33:36 UTC
From: Vojtech
Topic: 9469 Message: 9469

Hello.

I modeled a loop antenna with lumped components in LTspice. My loop is matched the same way as at the last picture on
http://www.w8ji.com/magnetic_receiving_loops.htm
Some call the matching a "voltage divider", although I doubt it works that way.

The loop element was modeled the simplest way as an impedance with series resistance. The result of simulation was, there is a parallel resonance of a very high real impedance at the antenna terminals and there is a series resonance of a low impedance. With careful tuning of both capacitors it is possible to achieve matching to 50 Ohms in series resonance. My understanding is, the loop is tuned by the parallel capacitor sidewise from its resonance frequency to act as an inductor, which is then resonated by the series tuning capacitor. My understanding is, there is little energy exchanged between the loop element and the parallel capacitor forth and back, the majority of energy bouncing happens between the loop element and the series capacitor. I suppose this is a bit naive observation, is it valid?

The results seem to be counter intuitive to me. Usually the loop is resonated to achieve parallel resonance, then the very high impedance is transformed to 50 Ohms with a secondary loop. This circuit certainly does not work the way it is often explained, that the matching tuning capacitor is a voltage divider to match the 50 Ohm real impedance to the loop in parallel resonance.

Is it required that the loop itself is tuned to resonance for the loop antenna to radiate?

I find it interesting that there are little experiments published trying to feed the loop at the capacitor side by transforming the high impedance down. Is it such a technical problem to wind a series of ferrite transformers?

Thanks and 73,
Vojtech OK1IAK

Many questions. I am probably not qualified to answer most of them.
But on this one:

> Is it required that the loop itself is tuned to resonance for the loop antenna to radiate?

No. That is a common (mis-)belief, but I assure you it is not true.
All wires carrying currents radiate, whether resonant or not.
Non-resonant antennas can and do make excellent radiators.

People like to tune them to resonance partly because it makes them
feel good, and partly because it is one step towards getting a nice
impedance for the feedline, and/or matching to the transmitter.
Having a large reactive component means the VSWR is not good, so
transmission line losses are higher.

(Even if it were somehow true that the loop element had to be resonant
in order to radiate, how would you accomplish that? The only way
would be to get out there and trim or add more wire, every time you
QSY. Adding a capacitor doesn't count. It doesn't alter the
resonance of the element itself. It just provides another path for
current to take *around* the radiating element. It changes the
appearance of resonance when looking from the feedline, but it does
not make the loop itself resonant. The loop doesn't know that there
is a capacitor there, all it knows is about the signal driving its
terminals, so it can't change whether or not it radiates based on
whether there is a capacitor or some other stuff connected to the
signal source.)

> I modeled a loop antenna with lumped components in LTspice.

I am puzzled how you did that. How did you represent the impedance of
the loop itself, which is changing vs. frequency? Depending on how
well you modeled that (it's not just a plain simple inductor, its size
is much too large for that), your simulation results might not very
well represent reality. People generally turn to tools such as NEC to
see what the antenna itself looks like, electrically.

> My understanding is, there is little energy exchanged between the loop
> element and the parallel capacitor forth and back, the majority of energy
> bouncing happens between the loop element and the series capacitor.
> I suppose this is a bit naive observation, is it valid?

My guess is: maybe, maybe not. It depends on the relative values of C1 and C2.

But I'm not sure if it matters.

I think in some cases it could be correct to think of the capacitors as a kind of lossless (well, low-loss) voltage divider. But it's not a simple voltage division either and you can get more voltage out than input. The point is, it's an impedance matching device, with two degrees of freedom, and two degrees of freedom are necessary to match complex impedance.

Andy

I have done some of this for wireless keyboards and mice operating at about 27 MHz.

First of all, you have to realize that there is NO reason to match to 50 Ohms at the receiving end. A box loop antenna is an inductor and capacitor in parallel, and will have a relatively high impedance (usually 3 to 5 k) on the real axis of a Smith Chart. But as long as the gain stage that follows has at least 10 time higher input impedance, the losses due to mismatch are negligible. This is true for all RF circuits - as long as you have a low impedance driving a high impedance, you will have little or no reflection, low SWR, and matching is not required.

Your application, of course, is transmit. Because your RF amplifier is probably designed to drive 50 Ohm loads, you are stuck with matching. Here is how I did it.

First determine the capacitance to resonate your loop exactly. This will put your box loop on the real axis, way to the right. It should be in the 3 to 5k range.

Back off on your capacitance to raise the point on the Smith Chart to about 20 degrees off axis.

Add a fixed resistor in series with the parallel RC until you get to the circle that will pass through 50 Ohms (most of the time normalized to "1" on the real axis) - the exact center of the chart.

Add a capacitor in parallel to the series R / parallel LC circuit to bring the resonance though the center of the Smith chart.

This is all from memory, from stuff I did 6 or 7 years ago, but I think that is how I did it. Done right, you will hit exactly 50 Ohms at your resonant frequency and energy transfer will be great into your antenna. You are doing a variation of this with your capacitor in series, the fixed resistor is a bit counter intuitive but believe me it works.

> ... This is true for all RF circuits - as long as you have a low
> impedance driving a high impedance, you will have little or no reflection,
> low SWR, and matching is not required.

Well, no, that is not true.

If there is some amount of transmission line (coax, feedline, etc.), and if it is a low impedance line driving a high impedance load, then you WILL get reflection, and high SWR.

But if the line lengths are short and the frequencies low enough so that the length is electrically short, then you can treat it as a low frequency circuit, and then the SWR that is on that short line may not bother you. Then, you can get maximum voltage at the load by connecting a high impedance load to the low impedance source. But you still do not get maximum power transfer except when the impedances match.

For reception of radio signals sent short distances, impedance mismatches (and consequent reception inefficiency) is OK because your received signals are so strong.

When the received signals are weaker, like they usually are in radio communications, it's a different story. We can often tolerate the mismatch+inefficiency on MF and HF because the atmospheric noise tends to dominate the signal-to-noise and everything is greater than the receiver's own noise, so some loss in received power (due to the mismatch) doesn't hurt the S/N ratio. But once you get up into VHF and above, you really need to match impedances between antenna and receiver because the receiver's noise is the limiting factor. A mismatch between the antenna and receiver causes signal loss and degraded S/N, and likely inability to receive weaker signals that you should have been able to receive.

> Add a fixed resistor in series with the parallel RC

I am guessing you meant to write inductor or capacitor, not resistor.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Magnet Wire from Radio Shack
This is what I use often
http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F011%5F010%5F004%5F000&product%5Fid=278%2D1345

Mouser Electronics
Mouser has the biggest spools here for a great price, that makes sense
http://www.mouser.com

Ocean State Electronics
magnet wire at a good price
http://www.oselectronics.com

WIRE "Flex-Weave" Antenna Wire
"Flex-Weave" is a hybrid aerial wire that consists of 168 strands of woven #36 solid copper wires that provide high strength and extreme flexibility. The most popular version of "Flex-Weave" is the 'equivalent' of #14 AWG wire size. It can be 'used' for unsupported spans up to 200 ft (100-150 ft in areas with high ice and wind loading).
http://www.radio-ware.com/products/fw.htm

WIRE "QuietFlex" Antenna Wire by Antennas & More: Insulated, Strong, Flexible and Durable
"QuietFlex" Antenna Wire by Antennas & More: "QuietFlex" #14 AWG Wire has more than 41 Strands tightly twisted together under its Flexible Insulation making it both Strong, Flexible and Durable.
http://www.antennasmore.com/wire&.htm

9480. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-12-01 16:46:46 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9480

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Wow, a Loop-Group and so few with information to share....

It must be that 160/80m Loops are so complicated and take so much work to put up that there are so few HAMs using them.

****
Has anyone 'modeled' or "USE" a full wave 160m loop? Using 450 ladder-line or coax?

My desire is to install a square 160m loop with ~75' of 450 ladder. The loop will almost be a prefect E/W-N/S square with the ladder-line coming off mid-east leg.

I'd like to know what the pattern will be with the loop 15', 20', 25', 30', 35' off the ground for the various bands? What the optimal height for this Loop for DX distances or USA distances.

I intend to install an Ugly-balun to see the cause-n-affects.

Does anyone have a 160m loop up? How high off the ground? How fed?
How does it work? Pro's & con's in using/building?

From what I've heard there may be some compromise in TX but it is a screamer on RX over all wires antennas (except multi-wave Rhombic).

Hello, I am doing a project on loop antennas and we are currently trying to construct one ourselves. We are following instructions from this site http://www.iw5edi.com/ham-radio/?how-to-build-a-tuned-loop-antenna,118

However, we substituted wood for PVC and our wires are the ones that comes in a pair and are encased in plastic. "Sound Physician Super OFC Silver Speaker Interconnect AWG-215.

We do not know the capacitance of the tuning capacitor we should use as the ones in the site says to use "a tuning capacitor salvaged from an old radio" which we do not have. Also since we modified some of the variables of the ones in the site, do you think it would affect the antenna?

Here are some pictures of the product now.

Using wood or PVC is not a problem. It is just a frame to hold the coil of wire in place. I prefer wood as I can use smaller/thinner pieces to save space.

Capacitor specifications are listed in the article as: "The capacitor that is used is the standard AM tuning capacitor with a range of 10 to 365pf." (There is also mention of using a dual-section capacitor to aid tuning.) Anything close will work. The plastic insulation of the speaker wire may also have an additional capacitive effect between turns of wire which will ultimately affect the L/C ratio (frequency response) of your loop so the number of turns of wire you use on your loop may differ from the article. Feel free to experiment. This is much like cooking where you have to adjust the recipe to work with what ingredients you have and your taste preferences. More turns of wire will peak up the lower frequencies. Less turns will get you into the shortwave frequencies. Have fun!

The foregoing advice is very good. Also, you may want to visit http://emclab.mst.edu/inductance/index.html . There you can choose the shape of the coil or loop. Click on the shape you want, and it will take you to a site where you can enter dimensions, wire radius, number of turns and permeability(enter 1 for air core windings). Then click on "L", and the inductance in nanoHenry's will be displayed. Move the decimal point three places to the left for microHenry's. Then go to http://www.daycounter.com/Calculators/LC-Resonance . There you will find an LC resonance calculator. The typical tuning capacitor from an old BC radio is 350pF - 400 pF. Some of these had an additional smaller section for the oscillator tank circuit of 180 pF - 200 pF or so. It might be interesting if you can find one of these to arrange to switch select one or the other or both. That way you might be able to tune from say 300 kHz to beyond 3 mHz with the same loop winding. I might add that if you have a good receiver with a 50 Ohm antenna input you can calculate how many microHy's are required for 50 Ohms at maybe 1 mHz and using the calculators referenced above construct a winding with enough turns for 50 Ohms at 1 mHz. Then wind that many turns spaced about 0.25 inch from the tuned winding and drive the receiver antenna input with the new winding. I arrived at the 0.25 inch spacing using LTSPICE modeling and a coefficient of coupling equation from the 1943 F. E. Terman Radio Engineer's Handbook.It works. Also, you can mount both windings on a lightweight wooden "cruciform" frame and use a a stereo phone plug as a bearing and connector. Then you have 360 degree rotation. But you may no longer have the classic pattern with two broad lobes. Try any or all of the above and build what works for you. Bill Young WD5HOH

For Medium Wave (AM Broadcast Band) This antenna uses a 365 pf variable capacitor. You can find one for a good price at www.midnightscience.com. When you are done building your loop, if you find that it does not tune all the way down to 540 KHz, add one turn to the loop. Conversely, if it does not tune all the way up to 1700 KHz, remove one turn. When you have the correct number of turns, the 365 pf variable capacitor should tune the entire AM broadcast band.

Good Luck,

Greg Ella

9492. Strange Loop Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-12-22 16:33:33 UTC
From: Greg Ella
Topic: 9492 Message: 9492

I have just created an album in the photo section and posted a photo of a strange antenna at the Denver International Airport.

I initially thought that this antenna was two crossed vertical loops mounted 90 degrees to each other. A closer look shows, as can be seen in the picture, that there are only three "halves" to the loop, instead of the four "halves" that you would have with two crossed loops. The three "halves" are symmetrical, 120 degrees apart when viewed from above. I don't think that this is a single "eggbeater" element, because when you zoom all the way in you can see that the sections appear to be insulated from each other.

This loop array is mounted above eight horizontal radials (only six visible in the photo). This could be a ground plane, but again, zooming in you see that each element appears to be mounted in an insulated connector. So this may be an array of horizontal crossed dipoles.

I visually guesstimate that the loop is at least 3 feet in diameter, and that each horizontal element is at least 12 feet long. It could be larger. It is mounted on top of a tall mast (at least 50 ft high), with no reference points to compare it to.

This antenna is located along the main entrance road to the airport. It is all by itself, well away from the tower, terminal, runways or any other antennas or structures. There is a landscaped rock area around the base of the mast, but no building or equipment shed.

I am a private pilot and am familiar with various antenna systems for VOR, ILS, NDB, voice comms, etc. I have never seen such an antenna before. It definitely appears to be of high quality commercial construction. This really has my curiosity going. Any information would be greatly appreciated.

Thanks,

Greg Ella

(snip)

I am guessing that this is a form of directable dipole antenna (the hoops being expanded folded dipoles.) If the three half hoops are independently fed, and phased, the radiation pattern could be shifted to have a major lobe in any compass direction. Perhaps the radials are also individually phased, to set the vertical beam angle, as the beam is rotated.

It is a very high tech looking radiator. I would love to see the manufacturer's specifications for it.

NDB beacon AP appears to be way south, below Centennial, at 39.452, -104.846. This antenna I have posted shows on Google Maps satellite view at 39.834894, -104.72322. Incidentally, you can zoom in to street view here and see the antenna in Google Maps street view. This is about 1000 ft South of the approach end of runway 7. It is not in line with any runway. When an NDB is placed near an airport it is usually on the extended centerline of a runway and about four miles out, to serve as a localizer for ADF approaches.

This could be their TIS antenna. I will have to see if FCC database shows that stations antenna location.

I am pretty sure this is their TIS antenna as my KML placemark for WPDI548 in my Google Earth version of my AM BCB logs puts my dot at 39.835230 and -104.722762 which is about 170 ft NE of the antenna mast in Google Earth which just about matches the coordinates you give below. The coordinates I got were originally from the FCC web site and were tweaked a little by me when I made my placemark.

I think that pretty much solves the use of the mystery antenna.

From: James
Topic: 9500 Message: 9500

My QTH is located about 1/2 to 1 mile from all TV, most FM, all Public Safety Radio transmitters. In the other direction, I have 4 AMBC stations. In effect, the perfect storm of overload. For example, I believe 91.5 and 96.5 FM can mix in an amplifier and create issues at 5 MHz. I have evaluated 7 different antennas systems with the following results:

1) 20 ft LW simply hanging on the end of a RG-59 feedline - pretty poor on all but local AM BC

2) 35 ft LW with 9:1 transformer - better but not great

3) Wellbrook AL-1530 Loop - good receive but its preamp impacted by local BC stuff

4) Wellbrook AL-330S Loop - good receive (not as good as 1530 at VLF-LF) Preamp better than 1530 but still impacted by local BC

5) Same as #4 but Type 31 Ferrite Choke added at premp feedpoint, coax grounded at 30 ft from Preamp - better overload performance

6) Clifton Labs Z1501D Whip with Same mods as #5 - best in all ways of #1 - 6 above but still some overload

7) Pixel PRO-1B "Moebius" Loop - only add-on was ground at 30 ft point but by far the best antenna. No overload whatsoever

By overload, I mean apparent effects on the antenna's LNA, not the receiver. Compression, IMD, errant mixing or whatever showed as odd stuff in my Perseus.

Subject: [loopantennas] Strange Loop Antenna

I have just created an album in the photo section and posted a photo of a strange antenna at the Denver International Airport.

I initially thought that this antenna was two crossed vertical loops mounted 90 degrees to each other. A closer look shows, as can be seen in the picture, that there are only three "halves" to the loop, instead of the four "halves" that you would have with two crossed loops. The three "halves" are symmetrical, 120 degrees apart when viewed from above. I don't think that this is a single "eggbeater" element, because when you zoom all the way in you can see that the sections appear to be insulated from each other.

This loop array is mounted above eight horizontal radials (only six visible in the photo). This could be a ground plane, but again, zooming in you see that each element appears to be mounted in an insulated connector. So this may be an array of horizontal crossed dipoles.

I visually guesstimate that the loop is at least 3 feet in diameter, and that each horizontal element is at least 12 feet long. It could be larger. It is mounted on top of a tall mast (at least 50 ft high), with no reference points to compare it to.

This antenna is located along the main entrance road to the airport. It is all by itself, well away from the tower, terminal, runways or any other antennas or structures. There is a landscaped rock area around the base of the mast, but no building or equipment shed.

I am a private pilot and am familiar with various antenna systems for VOR, ILS, NDB, voice comms, etc. I have never seen such an antenna before. It definitely appears to be of high quality commercial construction. This really has my curiosity going. Any information would be greatly appreciated.

Thanks,

Greg Ella

Greg, from your description of the device and it's location, coupled with the lack of any sort of nearby building and the landscaping at the base, could this be some sort of "modern sculpture" installed to "beautify" the aproaches to the airport? Could someone have sat down at a drawing board and designed this thing as part of a competition? There could also have been an interesting description as to what the 3 half-lobes might represent, the ground-plane could represent the land surface and the 3 curved bits could represent the 3 original Native Tribes of the area? Or could the designer have thought "well, this will get them thinking!"?
Merry Christmas from Australia!

the 1501 only suffered from I believe was ingress of FM (88-108) from the 5 or more stations down the street. That was manifested as a wide hump @ ~ 5 MHz with modulation "buried" in it.

9505. Re: [loopantennas] Re: Pixel vs. Wellbrook

Most Z1501D's and all Z1501F's have a low pass filter on the input stage providing about 15 dB roll off at 88 MHz. Without the LF filter, these antennas are usable to above 100 MHz. (As a special product, I can build Z1501's without the LP filter.)

I can't recall exactly when I added the LP filter to the D PCB, but not very many were sold without it and it has proven to be quite effective at eliminating FM mixing, even in dense urban areas.

The filter component values were chosen to preserve sensitivity while providing useful FM protection but it's possible to increase the FM roll off with some component changes. I don't recommend this be undertaken without the proper test gear, but any customer with an FM problem can contact me and I'll work with them. The current filter balances LF and shortwave performance against FM suppression, and increasing FM suppression will almost certainly reduce sensitivity in some other frequency bands. This reduction may well be acceptable however.

As an aside, the main problem in developing a useful FM band input filter relates to the rod antenna and whip amplifier impedance levels. Shunt capacitance (as in a pi filter configuration) isn't acceptable as every pF of extra shunt C hurts sensitivity. A conventional filter design also requires impossible to realize inductor values. Consequently, it's not a simple matter to add a "brick wall" FM band input filter.

Also, the new "F" version antenna uses a different input stage design, a dual gate FET instead of the J310 single gate of the D version. The dual gate device is somewhat better in FM interference rejection as well.

The Pixel loop amplifier (also a Clifton Laboratories design) has a very effective FM band input low pass filter (40 dB or more attenuation at 88 MHz) but that was much simpler since the impedance levels are (a) in the 50 ohm range and (b) more or less constant with frequency.

For a rough idea of AM and FM signal levels, you can use the signal predictor at http://www.v-soft.com/ZipSignal/ -- enter your ZIP code and the web site will calculate AM and FM field intensity levels. It's not 100% accurate, of course, but it remains quite useful.

Thanks for the reply Jack. This 1501 is pretty new and was a great unit except for the FM issue. I have made FS measurements here at my house and the FM and TV energy was incredible. So my FM issue is unusual. I have moved your whip to a more remote location and it is great.

I have 8, 10, 13, 21, 31 HDTV channels and a handle of low power TV on the hill. WDKX, WCMF, WXXI, WPXY and others live < 1/2 mile away (Pinnacle Hill) too. So my location is atypical.

9508. Edginton QW Loop beacon-test on 160 Meters

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-12-23 18:11:22 UTC
From: wb5wpa
Topic: 9508 Message: 9508

For the next couple of weeks, a test of a 160 meter Ben Edginton Quarter-Wave loop antenna will be underway.

The frequency will be 1900 kHz LSB up until about 5:30 PM CST and then 2.0 MHz LSB after that until about 10 PM CST.

The loop is 16' high x 40' long, stands vertically about 6' off the ground putting the highest part of the antenna about 22' above ground.

The loop is oriented roughly N-S (actually about 8 deg E of N).

Power level is 100 W max, with five transmitted tones varying from 100 Watts down to 1 Watt in 5 dB steps followed by voice ID.

The transmit interval is every 2 minutes, with the beacon 'message' being about 30 secs in length.

More details here as well as updates to the schedule:
http://www.qrz.com/db/WB5WPA

53, Jim WB5WPA

P.S. I hope this posting is allowed in this forum, if not, please disregard. Thanks in advance.

P.P.S. Preliminary testing has been on-going with this antenna and equipment since mid November.

9509. Loop Nulls

Has there been any published data regarding 'depth of null' vs 'loop aperture' concerning small circular receiving loops?
It has always been my gut-feeling that the smaller loops (< 4') had deeper and sharper nulls than larger loops (4-10')
but don't recall reading anything definitive.

Steve / VE7SL

9510. Re: [loopantennas] Loop Nulls

Topic: 9508 Message: 9510

I put some null depth data in my comparision of Pixel and Wellbrook. Not much difference between the two antennas for null depth. There's a huge problem with re-radiation from nearby conductors, however, in my case the ham radio tower and antennas. As the frequency increases above the middle of the AM broadcast band, re-radiation severely distorts my loop nulls. And, of course once you are dealing with sky wave signals the loop nulls become highly variable at best.

Document at
http://www.cliftonlaboratories.com/Documents/Loop%20vs%20Loop%20Final-Final.pdf

Does not address the large aperature question, but as far as I know my data is one of very few measured null plots for small loops in a real life environment.

FYI,

I copied your propagation test on 2.000 Mhz here in Cheyenne Wyoming..It appeared to be the 100 watt tones

were very weak at about S-2. However my antenna is 80/40 meter trap dipole, receiver is Kenwood TS-870.

Voice transmissions were not readable at this QTH. Reported at 1945 MDT, 12/23/12.

Good luck

WU7 G Jim

For the next couple of weeks, a test of a 160 meter Ben Edginton Quarter-Wave loop antenna will be underway.

The frequency will be 1900 kHz LSB up until about 5:30 PM CST and then 2.0 MHz LSB after that until about 10 PM CST.

The loop is 16' high x 40' long, stands vertically about 6' off the ground putting the highest part of the antenna about 22' above ground.

The loop is oriented roughly N-S (actually about 8 deg E of N).

Power level is 100 W max, with five transmitted tones varying from 100 Watts down to 1 Watt in 5 dB steps followed by voice ID.

The transmit interval is every 2 minutes, with the beacon 'message' being about 30 secs in length.

More details here as well as updates to the schedule:
http://www.qrz.com/db/WB5WPA

53, Jim WB5WPA

P.S. I hope this posting is allowed in this forum, if not, please disregard. Thanks in advance.

P.P.S. Preliminary testing has been on-going with this antenna and equipment since mid November.

Thanks Jack ....I have printed this out for careful reading. I am fairly familiar with re-radiation and nearby towers affecting null depth and direction but am more curious about the null sharpness / depth vs aperture and if there is any relationship or not.

> I put some null depth data in my comparision of Pixel and Wellbrook.

Thanks for the report, Jim

I had a report from east of Alexandria in Louisiana about
an hour ago ... individual was using a Degen 1103 portable
and copying the voice and tones ... that distance was only
about 300 miles though compared to the trip up to Cheyenne
Wyoming!

Thanks again for the report.

To Jim WB5WPA, Tonight(12/23/2012) just before 10:00 PM, CST I heard some of your tones, some of them at about S3 or so. I didn't have your entire message in front of me at the time, so I may have heard voice, but couldn't copy it. I have the details now and will try tomorrow evening. I am receiving you on an RX320D(TenTec) with a one foot square rotateable loop with two windings: one at about 50 Ohms driving the receiver and the other tuned and magnetically coupled to the first. My QTH is Harris County, Texas just slightly northwest of Houston. Bill Young WD5HOH

Thank you for the report Bill. Nice to see an in-state report far to the south! (QTH here of course being North-Central Texas/DFW area.)

Interesting antenna you describe using too.

I have set up to transmit on 1900 kHz again for the day until about 6 PM this evening (there are nets that meet on 1900) and then will QSY to 2 MHz again.

It would be interesting, Bill, if you get a chance to compare the signal strengths from the group that meets on 1990 kHz (every night starting about 7 PM) and in particular, how my signal compares with the W5VYY station as he is only a couple miles to my east and he runs a full-wave horizontal loop up about 75 feet (contrasted with the beacon QW vertical 16'x40' loop) and the W5VYY station tuns full legal power (whereas the beacon is 100 W max).

Could make for a useful comparison, the cloud-warmer FWLoop vs the low-radiation-angle vertical tuned QWLoop ...

9517. Loop diameter and frequency?

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-12-26 14:02:27 UTC
From: Scott Ehrlich
Topic: 9517 Message: 9517

I am about to build a magnetic loop with soft copper coil and dual stracor capacitor for the secondary loop.
I plan to work 7 - 30 mhz qrp with a Yaesu FT 817ND.

The local hardware store has a 10 foot coil in different inner diameters - 1/4 inch, 1/2 inch, 3/8 inch, etc.

The antenna will be used indoors only, likely on the second floor.

I am wondering two major things -

Does the diameter of the secondary really matter between 3 feet in diameter and 4 feet?

Does the inner diameter of 1/4 inch, 1/2 inch, etc really matter? I'd be tempted to get the largest diameter they have in stock.

I have ordered the capacitor - I know I could make one, but I found one for $25 including shipping.

For the coupling loop, I plan to use some good commercial-quality catv coax (rg58?), stripping off the outer coat and braided shielding.

Answers to the 3 or 4 foot diameter loop and inner diameters would be appreciated.

The 3 foot would be easiest, as the length (circumference) needs to be 9.6 feet (correct?) and the package comes as 10 feet (circumference) anyway.

Thanks.

Scott, WY1Z

IIRC the circumference of your loop should be no more than 1/3 wavelength for your highest frequency, longer being better for the low end. I honestly don't remember where I got that from but it is stuck in my mind from a few years ago when I made a similar antenna for < 20W duty.

I like the comment at the end about 3 D loops (not flat),
and their possibilities. Has anyone built a baseball seam loop?

Attachments: 1 described; binary payloads are missing from this source WARC

Evening Jim
I just got a shot of your W5VYY & Edington Loop signal comparison.

the blue line shows the signal peaks
the yellow was the instant I took the snap shot
the Big signal on the left is W5VYY
and the peaks right are the tones from your Edington loop

the bottom dotted yellow horizontal line is the S6 level
the purple side is the 2.8khz bandwidth of VFO B
and the green side is the 2.8khz bandwidth side of VFO B

again my receive conditions are:
my receiver is a K3
my antenna is a 7' tall Hi-Q 6/160 screwdriver loop at 20'
with 16 radials each 13' long

QRZ says you are located:
Bearing 62.3? ENE (from K5OAI)
Distance 252.5 mi (406.4 km)

hope this helps you see the comparison you were asking about the other day

not sure the attachment will come through to the list, but I'll give it a shot

9525. Introducing myself

Yahoo group: loopantennas (2008 — 2012)
Date: 2012-12-27 22:10:48 UTC
From: pu2clr
Topic: 9525 Message: 9525

Hello everybody.
My name is Ricardo.
After almost 30 years away from electronics I returned to this hobby.
I am a ham radio and also I like DX and SWL.

I ended up developing some projects about Antenna Magnetic Loop and Antenna Tuner.
So, I would like to share with you some videos on Youtube posted by me about my last projects:

Automatic Antenna Tuner for QRP controlled by Android and Arduino - Part 2
http://youtu.be/cZjbZRGTyVc

Automatic Antenna Tuner for QRP with Android and Arduino - Part 1
http://youtu.be/55bQ9xVWzuM

Magnetic Loop Antenna and infrared controlled by Arduino
http://youtu.be/b3hUpQvO38k

Best regards.
Thanks.
